Abstract

In this paper homomorphic cryptosystems are designed for the first time over any finite group. Applying Barrington's construction we produce for any boolean circuit of the logarithmic depth its encrypted simulation of a polynomial size over an appropriate finitely generated group.

1 Homomorphic cryptography over groups

1.1. Definitions and results. An important problem of modern cryptography concerns secret public-key computations in algebraic structures. There is a lot of public-key cryptosystems using groups (see e.g. [2, 10, 11, 12, 14, 15, 16, 21, 22] and also Subsection 1.3) but only a few of them have a homomorphic property in the sense of the following definition (cf. [11]).

Definition 1.1 *Let H be a finite nonidentity group, G a finitely generated group and $f : G \rightarrow H$ an epimorphism. Suppose that R is a right transversal of $\ker(f)$ in G , A is a set and $P : A \rightarrow G$ is a mapping such that $\text{im}(P) = \ker(f)$. A triple $\mathcal{S} = (A, P, R)$ is called a homomorphic cryptosystem over H with respect to f , if the following conditions are satisfied for a certain integer $N \geq 1$ (called the size of \mathcal{S}):*

(H1) *the elements of the set A are represented by words in a certain alphabet; one can get randomly an element of A of size N within probabilistic time $N^{O(1)}$,*

- (H2) *the elements of the group G are represented by words in a certain alphabet; one can test the equality of elements in G and perform group operations in G (taking the inverse and computing the product) in time $N^{O(1)}$, provided that the sizes of corresponding words are at most N ,*
- (H3) *the set R , the group H and the bijection $R \rightarrow H$ induced by f , are given by the list of elements, the multiplication table and the list of pairs $(r, f(r))$, respectively; $|R| = |H| = O(1)$,*
- (H4) *the mapping P is a trapdoor function (cf. [8]), i.e. given a word $a \in A$ of the length $|a|$ an element $P(a)$ can be computed within probabilistic time $|a|^{O(1)}$, whereas the problem $\text{INVERSE}(P)$ is computationally hard, while it can be solved by means of some additional secret information,*

where for any mapping $P : A \rightarrow G$ we define $\text{INVERSE}(P)$ to be the problem of testing whether given $g \in G$ belongs to $\text{im}(P)$ and yielding a random element $a \in A$ such that $P(a) = g$ whenever $g \in \text{im}(P)$.

Remark 1.2 *Having random generating in the set A one can easily generate elements of the group G in a form $P(a)r$, $a \in A$, $r \in R$.*

In a homomorphic cryptosystem \mathcal{S} the elements of H playing the role of the alphabet of plaintext messages are publically encrypted in a probabilistic manner by the elements of G playing the role of the alphabet of ciphertext messages, all the computations are performed in G and the result is decrypted to H . More precisely:

Public Key: homomorphic cryptosystem \mathcal{S} .

Secret Key: $\text{INVERSE}(P)$.

Encryption: given a plaintext $h \in H$ encrypt as follows: take $r \in R$ such that $f(r) = h$ (invoking (H3)) and a random element $a \in A$ (using (H1)); the ciphertext of h is the element $P(a)r$ of G (computed by means of (H2) and (H4)).

Decryption: given a ciphertext $g \in G$ decrypt as follows: find the elements $r \in R$ and $a \in A$ such that $rg^{-1} = P(a)$ (using (H4)); the plaintext of g is the element $f(r)$ of H (computed by means of (H3)).

The main result of the present paper consists in the construction of a homomorphic cryptosystem over arbitrary finite nonidentity group; the security of it is based on the difficulty of the following slight generalization of the factoring problem $\text{FACTOR}(n, m)$: given a positive integer $n = pq$ with p and q being primes (of the same size), a number $m \geq 2$ of a constant size such that $G/(\mathbb{Z}_n^*)^m \cong \mathbb{Z}_m^+$ where $G = \{g \in \mathbb{Z}_n^* : \mathbf{J}_n(g) \in$

$\{1, (-1)^{m \pmod{2}}\}$ with \mathbf{J}_n being the Jacobi symbol, and a transversal of $(\mathbb{Z}_n^*)^m$ in G , find the numbers p, q . In addition, we assume that $m \mid p-1$ and $\text{GCD}(m, q-1) = \text{GCD}(m, 2)$, although one could get rid of this extra assumption.

Theorem 1.3 *Let H be a finite nonidentity group and $N \in \mathbb{N}$. Then one can design a homomorphic cryptosystem $\mathcal{S}(H, N)$ of the size $O(N)$ over the group H ; the problem $\text{INVERSE}(P)$ where P is the trapdoor function, is probabilistic polynomial time equivalent to the problems $\text{FACTOR}(n, m)$ for appropriate $n = \exp(O(N))$ and m running over the divisors of $|H|$.*

First this result is proved for a cyclic group H (see Section 2), in this case the group G being a finite Abelian group. Then in Section 3 a homomorphic cryptosystem is yielded for an arbitrary H , in this case the group G being a free product of certain Abelian groups produced in Section 2. In Section 4 we recall the result from [1] designing a polynomial size simulation of any boolean circuit B of the logarithmic depth over an arbitrary unsolvable group H (in particular, one can take H to be the symmetric group $\text{Sym}(5)$). Combining this result with Theorem 1.3 provides an *encrypted simulation* of B over the group G : the output of this simulation at a particular input is a certain element $g \in G$, and thereby to know the output of B one has to be able to calculate $f(g) \in H$, which is supposedly to be difficult due to Theorem 1.3. We mention that a different approach to encrypt boolean circuits was undertaken in [24].

1.2. Discussion on complexity and security. One can see that the encryption procedure can be performed by means of public keys efficiently. However, the decryption procedure is a secret one in the following sense. To find the element r one has to solve in fact, the membership problem for the subgroup $\ker(f)$ of the group G . We assume that a solution for each instance $g' \in \ker(f)$ of this problem must have a “proof”, which is actually an element $a \in P^{-1}(g')$. Thus, the secrecy of the system is based on the assumption that finding an element in the set $P^{-1}(g')$ i.e. solving $\text{INVERSE}(P)$ is an intractable computation problem. On the other hand, our ability to compute P^{-1} enables us to efficiently implement the decryption algorithm. One can treat P as a proof system for membership to $\ker(f)$ in the sense of [3]. Moreover, in case when A is a certain group and P is a homomorphism we have the following *exact* sequence of group homomorphisms

$$A \xrightarrow{P} G \xrightarrow{f} H \rightarrow \{1\} \quad (1)$$

(recall that the exact sequence means that the image of each homomorphism in it coincides with the kernel of the next one).

The usual way in the public-key cryptography of providing an evidence of the security of a cryptosystem is to fix a certain type of an attack (being an algorithm) of cryptosystems and to prove that a cryptosystem is resistant with respect to this type of an attack. The

resistancy means usually that breaking a cryptosystem with the help of the fixed type of an attack implies a certain statement commonly believed to be unplausable. The most frequently used in the cryptography such statement (which we involve as well) is the possibility to factorize an integer being a product of a pair of primes. Thus a type of an attack we fix is that to break a homomorphic cryptosystem means to be able to solve $\text{INVERSE}(P)$ (in other words, reveal the trapdoor).

Notice that in the present paper the group H is always rather small, while the group G could be infinite but being always finitely generated. However, the infiniteness of G is not an obstacle for performing algorithms of encrypting and decrypting (using the trapdoor information) since G is a free product of groups of a number-theoretic nature like \mathbb{Z}_n^* ; therefore one can easily verify the condition (H2) and on the other hand this allows one to provide evidence for the difficulty of a decryption. In this connection we mention a public-key cryptosystem from [6] in which f was the natural epimorphism from a free group G onto the group H (infinite, non-abelian in general) given by generators and relations. In this case for any element of H one can produce its preimages (encryptions) by inserting in a word (being already a produced preimage of f) from G any relation defining H . In other terms, decrypting of f reduces to the word problem in H . In our approach the word problem is solvable easily due to a special presentation of the group G (rather than given by generators and relations).

1.3. Cryptosystems based on groups. To our best knowledge all known at present homomorphic cryptosystems are more or less modifications of the following one. Let n be the product of two distinct large primes of size of the order $\log n$. Set $G = \{g \in \mathbb{Z}_n^* : \mathbf{J}_n(g) = 1\}$ and $H = \mathbb{Z}_2^+$. Then given a non-square $r \in G$ the triple (A, P, R) where

$$R = \{1, r\}, \quad A = \mathbb{Z}_n^*, \quad P(g) : g \mapsto g^2,$$

is a homomorphic cryptosystem over H with respect to the natural epimorphism $f : G \rightarrow H$ with $\ker(f) = \{g^2 : g \in \mathbb{Z}_n^*\}$ (see [9, 8]). We call it the *quadratic residue cryptosystem*. It can be proved (see [9, 8]) that in this case solving the problem $\text{INVERSE}(P)$ is not easier than factoring n , whereas given a prime divisor of n this problem can be solved in probabilistic polynomial time in $\log n$.

It is an essential assumption (being a shortcoming) in the quadratic residue cryptosystem as well as other cryptosystems cited below that its security relies on a fixed a priori (proof system) P . Indeed, it is not excluded that an adversary could verify whether an element of G belongs to $\ker(f)$ avoiding making use of P , for example, in case of the quadratic residue cryptosystem that would mean verifying that $g \in G$ is a square without providing a square root of g . Although, there is a common conjecture that verifying for an element to be a square (as well as some power) is also difficult.

Let us mention that a cryptosystem from [19] over $H = \mathbb{Z}_n^+$ (for the same assumptions on n as in the quadratic residue cryptosystem) with respect to the homomorphism $f :$

$G \rightarrow H$ where $G = \mathbb{Z}_{n^2}^*$ and $\ker(f) = \{g^n : g \in G\}$, in which $A = G$ and $P : g \mapsto g^n$, is not homomorphic in the sense of Definition 1.1 because condition (H3) of it does not hold. (In particular, since $|G| \leq |H|^2$, one can inverse P in a polynomial time in $|H|$.) By the same reason the cryptosystem from [17] over $H = \mathbb{Z}_p^+$ with respect to the homomorphism $f : G \rightarrow H$ where $G = \mathbb{Z}_{p^2q}^*$ and $\ker(f) = \{g^{pq} : g \in G\}$ (here the integers p, q are distinct large primes of the same size) is also not homomorphic (besides, in this system only a part of the group H is encrypted). Some cryptosystems over certain dihedral groups were studied in [21]. More general, in [11] homomorphic cryptosystems were designed over an arbitrary nonidentity solvable group.

We note in addition that an alternative setting of a homomorphic (in fact, isomorphic) encryption E (and a decryption $D = E^{-1}$) was proposed in [14]. Unlike Definition 1.1 the encryption $E : G \rightarrow G$ is executed in the same set G (being an elliptic curve over the ring \mathbb{Z}_n) treated as the set of plaintext messages. If n is composite, then G is not a group while being endowed with a partially defined binary operation which converts G in a group when n is prime. The problem of decrypting this cryptosystem is close to the factoring of n . In this aspect [14] is similar to the well-known RSA scheme (see e.g. [8]) if to interpret RSA as a homomorphism (in fact, isomorphism) $E : \mathbb{Z}_n^* \rightarrow \mathbb{Z}_n^*$, for which the security relies on the difficulty of finding the order of the group \mathbb{Z}_n^* .

We complete the section by mentioning some cryptosystems using groups but not being homomorphic in the sense of Definition 1.1. The well-known example is a cryptosystem which relies on the Diffie-Hellman key agreement protocol (see e.g. [8]). It involves cyclic groups and relates to the discrete logarithm problem [15]; the complexity of this system was studied in [4]. Some generalizations of this system to non-abelian groups (in particular, the matrix groups over some rings) were suggested in [18] where secrecy was based on an analog of the discrete logarithm problems in groups of inner automorphisms. Certain variations of the Diffie-Hellman systems over the braid groups were described in [12]; here several trapdoor one-way functions connected with the conjugacy and the taking root problems in the braid groups were proposed. Finally it should be noted that a cryptosystem from [16] is based on a monomorphism $\mathbb{Z}_m^+ \rightarrow \mathbb{Z}_n^*$ by means of which x is encrypted by $g^x \pmod{n}$ where n, g constitute a public key; its decrypting relates to the discrete logarithm problem and is feasible in this situation due to a special choice of n and m (cf. also [2]).

2 Homomorphic cryptosystems over cyclic groups

In this section we present an explicit homomorphic cryptosystem over a cyclic group of an order $m > 1$ whose decryption is based on taking m -roots in the group \mathbb{Z}_n^* for a suitable $n \in \mathbb{N}$. It can be considered in a sense as a generalization of the quadratic residue cryptosystem over \mathbb{Z}_2^+ . Throughout this section given $n \in \mathbb{N}$ we denote by $|n|$ the size of

the number n .

Given a positive integer $m > 1$ denote by D_m the set of all pairs (p, q) where p and q are distinct odd primes such that

$$p - 1 = 0 \pmod{m} \quad \text{and} \quad \text{GCD}(m, q - 1) = \text{GCD}(m, 2). \quad (2)$$

Let $(p, q) \in D_m$, $n = pq$ and $G_{n,m}$ be a group defined by

$$G_{n,m} = \{g \in \mathbb{Z}_n^* : \mathbf{J}_n(g) \in \{1, (-1)^{m \pmod{2}}\}\}. \quad (3)$$

Thus $G_{n,m} = \mathbb{Z}_n^*$ for an odd m and $[\mathbb{Z}_n^* : G_{n,m}] = 2$ for an even m . In any case this group contains each element $h = h_p \times h_q$ such that $\langle h_p \rangle = \mathbb{Z}_p^*$ and $\langle h_q \rangle = \mathbb{Z}_q^*$ where h_p and h_q are the p -component and the q -component of h with respect to the canonical decomposition $\mathbb{Z}_n^* = \mathbb{Z}_p^* \times \mathbb{Z}_q^*$. From (2) it follows that m divides the order of any such element h and $\{1, h, \dots, h^{m-1}\}$ is a transversal of the group $G_{n,m}^m = \{g^m : g \in G_{n,m}\}$ in $G_{n,m}$. This implies that $G_{n,m}/G_{n,m}^m \cong \mathbb{Z}_m^+$ where the corresponding epimorphism is given by the mapping

$$f_{n,m} : G_{n,m} \rightarrow \mathbb{Z}_m^+, \quad g \mapsto i_g$$

with i_g being the element of \mathbb{Z}_m^+ such that $g \in G_{n,m}^m h^{i_g}$. From (2) it follows that $\ker(f_{n,m}) = G_{n,m}^m = \text{im}(P_{n,m})$ where

$$P_{n,m} : A_{n,m} \rightarrow G_{n,m}, \quad g \mapsto g^m$$

is a homomorphism from the group $A_{n,m} = \mathbb{Z}_n^*$ to the group $G_{n,m}$. In particular, we have the exact sequence (1) with $A = A_{n,m}$, $P = P_{n,m}$, $f = f_{n,m}$, $G = G_{n,m}$ and $H = \mathbb{Z}_m^+$. Next, it is easily seen that any element of the set

$$\mathcal{R}_{n,m} = \{R \subset G_{n,m} : |f_{n,m}(R)| = |R| = m\}$$

is a right transversal of $G_{n,m}^m$ in $G_{n,m}$. We notice that by the Dirichlet theorem on primes in arithmetic progressions (see e.g. [5]) the set D_m is not empty. Moreover, by the same reason the set

$$D_{N,m} = \{n \in \mathbb{N} : n = pq, (p, q) \in D_m, |p| = |q| = N\}$$

is also nonempty for sufficiently large $N \in \mathbb{N}$.

Theorem 2.1 *Let H be a cyclic group of order $m > 1$. Then given $N \in \mathbb{N}$ and $n \in D_{N,m}$ one can design a homomorphic cryptosystem $\mathcal{S}_n(H, N)$ of the size $O(N)$ over the group H ; the problem $\text{INVERSE}(P)$ where P is the trapdoor function, is probabilistic polynomial time equivalent to the problem $\text{FACTOR}(n, m)$.*

Proof. First we describe a probabilistic polynomial time algorithm which yields a certain $n \in D_{N,m}$. The algorithm picks randomly integers $p = 1 \pmod{m}$ and $q = -1 \pmod{m}$ from the interval $[2^N, 2^{N+1}]$ and tests primality of the picked numbers by means of e.g. [23]. According to [5] there is a constant $c > 0$ such that for any b relatively prime with m there are at least $c2^N/(\varphi(m)N)$ primes of the form $mx + b$ in the interval $[2^N, 2^{N+1}]$. Therefore, after $O(N)$ attempts the algorithm would yield a pair $(p, q) \in D_m$ with a probability greater than $2/3$ (actually, one can replace $2/3$ by an arbitrary constant less than 1). Thus given $N \in \mathbb{N}$ one can design in probabilistic time $N^{O(1)}$ a number $n \in D_{N,m}$, a random element $R \in \mathcal{R}_{n,m}$ (see e.g. [16]) and the triple

$$\mathcal{S}_n(H, N) = (A, P, R) \quad (4)$$

where $A = A_{n,m}$ and $P = P_{n,m}$ (below without loss of generality we assume that $H = \mathbb{Z}_m^+$).

We will show that for any $n \in D_{N,m}$ and $R \in \mathcal{R}_{n,m}$ the triple $\mathcal{S}_n(H, N)$ is a homomorphic cryptosystem of the size $O(N)$ over the group H with respect to the epimorphism $f : G \rightarrow H$ where $f = f_{n,m}$ and $G = G_{n,m}$. For this purpose we note that in this case there is the exact sequence (1) (see above). Next, we will represent the elements of the set A and of the group G by integers modulo n , and those of the group H by integers modulo m . Then conditions (H1), (H2) and (H3) of Definition 1.1 are trivially satisfied. Since the epimorphism P is obviously a polynomial time computable one, it suffices to verify condition (H4), i.e. that the problems $\text{INVERSE}(P)$ and $\text{FACTOR}(n, m)$ are probabilistic polynomial time equivalent.

Suppose that we are given an algorithm solving the problem $\text{FACTOR}(n, m)$. Then we can find the decomposition $n = pq$. Now using Rabin's probabilistic polynomial-time algorithm for finding roots of polynomials over finite prime fields (see [20]), we can solve the problem $\text{INVERSE}(P)$ for an element $g \in G$ as follows:

Step 1. Find the numbers $g_p \in \mathbb{Z}_p^*$ and $g_q \in \mathbb{Z}_q^*$ such that $g = g_p \times g_q$, i.e. $g_p = g \pmod{p}$, $g_q = g \pmod{q}$.

Step 2. Apply Rabin's algorithm for the field of order p to the polynomial $x^m - g_p$ and for the field of order q to the polynomial $x^m - g_q$. If at least one of this polynomials has no roots, then output " $P^{-1}(g) = \emptyset$ "; otherwise let h_p and h_q be corresponding roots.

Step 3. Output " $P^{-1}(g) \neq \emptyset$ " and $h = h_p \times h_q$.

We observe that the set $P^{-1}(g)$ is empty, i.e. the g is not an m -power in G , iff at least one of the elements g_p and g_q found at Step 1 is not an m -power in \mathbb{Z}_p^* and \mathbb{Z}_q^* respectively. This implies the correctness of the output at Step 2. On the other hand, if the procedure

terminates at Step 3, then $h^m = h_p^m \times h_q^m = g_p \times g_q = g$, i.e. $h \in P^{-1}(g)$. Thus the problem $\text{INVERSE}(P)$ is reduced to the problem $\text{FACTOR}(n, m)$ in probabilistic time $N^{O(1)}$.

Conversely, suppose that we are given an algorithm solving the problem $\text{INVERSE}(P)$. Then the following procedure using well-known observations [8] enables us to find the decomposition $n = pq$.

Step 1. Randomly choose $g \in \mathbb{Z}_n^*$. Set $T = \{g\}$.

Step 2. While $|T| < 3 - (m \bmod 2)$, add to T a random m -root of the element g^m yielded by the algorithm for the problem $\text{INVERSE}(P)$.

Step 3. Choose $h_1, h_2 \in T$ such that $q = \text{GCD}(h_1 - h_2, n) \neq 1$. Output q and $p = n/q$.

To prove the correctness of the procedure we observe that there exists at least 2 (resp. 4) different m -roots of the element g^m for odd m (resp. for even m) where g is the element chosen at Step 1. So the loop at Step 2 and hence the entire procedure terminates with a large probability after a polynomial number of iterations. Moreover, let $T_q = \{h_q : h \in T\}$ where h_q is the q -component of h . Then from (2) it follows that $|T_q| = 1$ for odd m , and $|T_q| \leq 2$ for even m . Due to the construction of T at Step 2 this implies that there exist different elements $h_1, h_2 \in T$ such that $(h_1)_q = (h_2)_q$, and consequently

$$h_1 = (h_1)_q = (h_2)_q = h_2 \pmod{q}.$$

Since $h_1 \neq h_2 \pmod{n}$, we conclude that $h_1 - h_2$ is a multiple of q and output at Step 3 is correct. ■

We complete the section by mentioning that the decryption algorithm of the homomorphic cryptosystem $\mathcal{S}_{N,m,n}$ can be slightly modified to avoid applying Rabin's algorithm for finding roots of polynomials over finite fields. Indeed, it is easy to see that an element $g = g_p \times g_q$ of the group G belongs to the group G^m iff $g_p^{(p-1)/m} = 1 \pmod{p}$ and $g_q^{(q-1)/m'} = 1 \pmod{q}$ where $m' = \text{GCD}(m, q-1)$.

3 Homomorphic cryptosystems using free products

Throughout the section we denote by W_X the set of all the words w in the alphabet X ; the length of w is denoted by $|w|$. We use the notation $G = \langle X; \mathcal{R} \rangle$ for a presentation of a group G by the set X of generators and the set \mathcal{R} of relations. Sometimes we omit \mathcal{R} to stress that the group G is generated by the set X . The unity of G is denoted by 1_G and we set $G^\# = G \setminus \{1_G\}$. Finally, given a positive integer n we set $\bar{n} = \{1, \dots, n\}$.

3.1. Calculations in free products of groups. Let us remind the basic facts on free products of groups (see e.g. [13, Ch. 4]). Let G_1, \dots, G_n be finite groups, $n \geq 1$. Given a presentation $G_i = \langle X_i; \mathcal{R}_i \rangle$, $i \in \bar{n}$, one can form a group $G = \langle X; \mathcal{R} \rangle$ where $X = \cup_{i \in \bar{n}} X_i$ (the disjoint union) and $\mathcal{R} = \cup_{i \in \bar{n}} \mathcal{R}_i$. It can be proved that this group does not depend on the choice of presentations of $\langle X_i; \mathcal{R}_i \rangle$, $i \in \bar{n}$. It is called the *free product* of the groups G_i and is denoted by $G = G_1 * \dots * G_n$; one can see that it does not depend on the order of factors. Without loss of generality we assume below that G_i is a subgroup of G and $X_i = G_i^\#$ for all i . In this case $G \subset W_X$ and 1_G equals the empty word of W_X . Moreover, it can be proved that

$$G = \{x_1 \cdots x_k \in W_X : x_j \in G_{i_j} \text{ for } j \in \bar{k}, \text{ and } i_j \neq i_{j+1} \text{ for } j \in \overline{k-1}\}. \quad (5)$$

Thus each element of G is a word of W_X in which no two adjacent letters belong to the same set among the sets X_i , and any two such different words are different elements of G . To describe the multiplication in G let us first define recursively the mapping $W_X \rightarrow G$, $w \mapsto \overline{w}$ as follows

$$\overline{w} = \begin{cases} w, & \text{if } w \in G, \\ \overline{\dots(x \cdot y)\dots}, & \text{if } w = \dots xy \dots \text{ with } x, y \in X_i \text{ for some } i \in \bar{n}, \end{cases} \quad (6)$$

where $x \cdot y$ is the product of x by y in the group G_i . One can prove that the word \overline{w} is uniquely determined by w and so the mapping is correctly defined. In particular, this implies that given $i \in \bar{n}$ we have

$$\overline{x_1 \cdots x_k} \in G_i \Leftrightarrow \overline{x_1 \cdots x_k} = \overline{x_{j_1} \cdots x_{j_{k'}}} \quad (7)$$

where $\{j_1, \dots, j_{k'}\} = \{j \in \bar{k} : x_j \in G_i\}$. Now given $g, h \in G$ the product of g by h in G equals gh .

Lemma 3.1 *Let $G = G_1 * \dots * G_n$, $K = K_1 * \dots * K_n$ be groups and f_i be an epimorphism from G_i onto K_i , $i \in \bar{n}$. Then the mapping*

$$\varphi : G \rightarrow K, \quad x_1 \cdots x_k \mapsto \overline{f_{i_1}(x_1) \cdots f_{i_k}(x_k)} \quad (8)$$

where $x_j \in G_{i_j}$, $j \in \bar{k}$, is an epimorphism. Moreover, $\varphi|_{G_i} = f_i$ for all $i \in \bar{n}$.

Proof. Since $K = \langle Y \rangle$ where $Y = \cup_{i \in \bar{n}} K_i^\#$, the surjectivity of the mapping φ follows from the surjectivity of the mappings f_i , $i \in \bar{n}$. Next, let $\varphi_0 : W_X \rightarrow W_Y$ be the mapping taking $x_1 \cdots x_k$ to $f_{i_1}(x_1) \cdots f_{i_k}(x_k)$. Then it is easy to see that $\varphi(g) = \overline{\varphi_0(g)}$ for all $g \in G$ and $\varphi_0(w w') = \varphi_0(w) \varphi_0(w')$ for all $w, w' \in W_X$. Since $\overline{\overline{w} \overline{w'}} = \overline{w w'}$ for all $w, w' \in W_X$, this implies that

$$\overline{\varphi(g) \varphi(h)} = \overline{\overline{\varphi_0(g)} \overline{\varphi_0(h)}} = \overline{\varphi_0(g) \varphi_0(h)} = \overline{\varphi_0(gh)} = \overline{\varphi(gh)} = \varphi(\overline{gh})$$

for all $g, h \in G$. Thus the mapping φ is a homomorphism. Since obviously $\varphi|_{G_i} = f_i$ for all $i \in \overline{n}$, we are done. ■

Let H be a finite nonidentity group and K be the free product of cyclic groups generated by all the nonidentity elements of H . Set

$$\begin{aligned}\mathcal{R}^{(0)} &= \{h^{(m_h)} \in W_{H^\#} : h \in H^\#\}, \\ \mathcal{R}^{(1)} &= \{h^{(i)}h' \in W_{H^\#} : h, h' \in H^\#, 0 < i < m_h, h^i \cdot h' = 1_H\}, \\ \mathcal{R}^{(2)} &= \{hh'h'' \in W_{H^\#} : h, h', h'' \in H^\#, h' \notin \langle h \rangle, h \cdot h' \cdot h'' = 1_H\}\end{aligned}$$

where $h^{(i)}$ is the word of length $i \geq 1$ with all letters being equal h , m_h is the order of $h \in H$ and \cdot denotes the multiplication in H . Then one can see that

$$K = \langle H^\#; \mathcal{R}^{(0)} \rangle \quad (9)$$

and there is the natural epimorphism $\psi' : K \rightarrow H'$ where $H' = \langle H^\#; \mathcal{R}^{(0)} \cup \mathcal{R}^{(1)} \cup \mathcal{R}^{(2)} \rangle$. Since relations belonging to $\mathcal{R}^{(i)}$, $i = 0, 1, 2$, are satisfied in H , we conclude that $\ker(\psi')h_1 \neq \ker(\psi')h_2$ whenever h_1 and h_2 are different elements of H (we identify 1_K and 1_H). On the other hand, it is easy to see that any right coset of K by $\ker(\psi')$ contains a word of length at most 1, i.e. an element of H . Thus $K = \cup_{h \in H} \ker(\psi')h$, the mapping

$$\psi : K \rightarrow H, \quad k \mapsto h_k \quad (10)$$

where h_k is the uniquely determined element of H for which $k \in \ker(\psi')h_k$, is an epimorphism and $\ker(\psi) = \ker(\psi')$.

3.2. Main construction of a homomorphic cryptosystem. Let H be a finite nonidentity group and N be a positive integer. We are going to describe a homomorphic cryptosystem $\mathcal{S}(H, N)$ of size $O(N)$ over the group H . Suppose first that H is a cyclic group of an order $m > 1$. Then we set $\mathcal{S}(H, N) = \mathcal{S}_n(H, N)$ where $n \in D_{N, m}$ (see Theorem 2.1). If H is not a cyclic group, then $\mathcal{S}(H, N)$ is defined as follows.

Let $H^\# = \{h_1, \dots, h_n\}$ where n is a positive integer (clearly, $n \geq 3$). Set $D_{N, H} = \cup_{i \in \overline{n}} D_{N, m_i}$ where m_i is the order of the group $K_i = \langle h_i \rangle$. Given $i \in \overline{n}$ choose $n_i \in D_{N, m_i}$ and set $\mathcal{S}_i = (A_i, P_i, R_i)$ to be the homomorphic cryptosystem $\mathcal{S}_{n_i}(K_i, N)$ with respect to the epimorphism $f_i : G_i \rightarrow K_i$ (see Theorem 2.1). Without loss of generality we assume that G_i is a subgroup of the group $\mathbb{Z}_{n_i}^*$. Set

$$G = G_1 * \dots * G_n, \quad f = \psi \circ \varphi, \quad (11)$$

where the mappings φ and ψ are defined by (8) and (10) respectively, with $K = K_1 * \dots * K_n$. From Lemma 3.1 and the definition of ψ it follows that the mapping $f : G \rightarrow H$ is an epimorphism from G onto H .

To define a proof system for membership to $\ker(f)$ (see Subsection 1.2) we set

$$X_\varphi = X \cup A_0 \quad X = \cup_{i \in \bar{n}} G_i \setminus \ker(f_i), \quad A_0 = \cup_{i \in \bar{n}} A_i, \quad (12)$$

all the unions are assumed to be the disjoint ones. Denote by \rightarrow the transitive closure of the binary relation \Rightarrow on the set W_{X_φ} defined by

$$v \Rightarrow w \quad \text{iff} \quad w = x^{-1}x_0vx, \quad v, w \in W_{X_\varphi} \quad (13)$$

where $x \in X \cup \{1_A\}$ and $x_0 \in A_0 \cup \{1_A\}$ with 1_A being the empty word of W_{X_φ} . Thus $v \rightarrow w$ if there exist words $w_1 = v, w_2, \dots, w_l = w$ of W_{X_φ} such that $w_i \Rightarrow w_{i+1}$ for $i \in \overline{l-1}$. We set

$$A_\varphi = \{a \in W_{X_\varphi} : 1_{A_\varphi} \rightarrow a\}, \quad P_\varphi : A_\varphi \rightarrow G, \quad a_1 \cdots a_k \mapsto \overline{P_\varphi(a_1) \cdots P_\varphi(a_k)} \quad (14)$$

where $P_\varphi|_X = \text{id}_X$ and $P_\varphi|_{A_i} = P_i$ for all i . We observe that if $\bar{v} \in \ker(\varphi)$ and $v \Rightarrow w$ for some $v, w \in W_{X_\varphi}$ then obviously $\bar{w} \in \ker(\varphi)$ (see (13)). By induction on the size of a word this implies that $P_\varphi(A_\varphi) \subset \ker(\varphi)$. Next, set

$$A_\psi = \{r \in W_{R_\psi} : f(\bar{r}) = 1_H\}, \quad P_\psi : A_\psi \rightarrow G, \quad a \mapsto \bar{a} \quad (15)$$

where $R_\psi = \cup_{i \in \bar{n}} R_i$. It is easily seen that the restriction of φ to the set $R_\varphi = G \cap W_R$ induces a bijection from this set to the group K . This shows that R_φ is a right transversal of $\ker(\varphi)$ in G . Finally we define

$$A = A_\varphi \times A_\psi, \quad P : A \rightarrow G, \quad (a, b) \mapsto \overline{P_\varphi(a)P_\psi(b)}. \quad (16)$$

Let R be a right transversal of $\ker(f)$ in G , for instance one can take $R = \{1_G\} \cup \{r'_i\}_{i \in \bar{n}}$ where r'_i is the element of R_i such that $\psi(r'_i) = h_i$, $i \in \bar{n}$. Set $\mathcal{S}(H, N) = (A, P, R)$.

3.3. Proof of Theorem 1.3.

First we observe that if H is a cyclic group, then the required statement follows from Theorem 2.1. Suppose from now on that the group H is not cyclic. Let us describe the presentations of the set A and the groups G and K . Given $i \in \bar{n}$ the elements $a \in A_i$ and $g \in G_i$ being the elements of $\mathbb{Z}_{n_i}^*$ will be represented by the “letters” $]a, i[$ and $[g, i]$ respectively. This completely defines the representations of the set A and the group G . We note that relying on (13), (14) and (15) one can randomly generate elements of A .

The group G is represented by the subset (5) of the set W_X . To multiply two elements $g, h \in G$ one has to find the word \overline{gh} of W_X . It is easy to see that this can be done by means of the recursive procedure (6) in time $((|g| + |h|)N)^{O(1)}$ (here $[x, i] \cdot [y, i] = [xy, i]$ for all $x, y \in \mathbb{Z}_{n_i}^*$ where xy is the product modulo n_i of the numbers x and y , and $n_i \leq \exp^{O(N)}$ because $n_i \in D_{N, m_i}$). Since taking the inverse of $g \in G$ can be easily implemented in time

$(|g|N)^{O(1)}$, we will estimate further the running time of the algorithms via the number of performed group operations in G and via the sizes of the involved operands.

Finally the group H as well as the groups K_i , $i \in \bar{n}$, are given by their multiplication tables, and the group K is given by the presentation (9). Thus all the group operations in K can be performed in time polynomial in the lengths of the input words belonging to $W_{H\#}$.

Now, we have the following sequence of the mappings:

$$A_\varphi \times A_\psi \xrightarrow{P} G_1 * \cdots * G_n \xrightarrow{\varphi} K_1 * \cdots * K_n \xrightarrow{\psi} H.$$

In the following two lemmas we study the homomorphisms φ and ψ from the algorithmic point of view.

Lemma 3.2 *For the mapping P_φ defined in (14) the following statements hold:*

- (i1) *given $a \in A_\varphi$ the element $P_\varphi(a)$ can be found in time $|a|^{O(1)}$,*
- (i2) $\text{im}(P_\varphi) = \ker(\varphi)$,
- (i3) *given an oracle Q_i for the problem $\text{INVERSE}(P_i)$ for all $i \in \bar{n}$, the problem $\text{INVERSE}(P_\varphi)$ for $g \in G$ can be solved by means of at most $|g|^2$ calls of oracles Q_i , $i \in \bar{n}$,*
- (i4) *for each $i \in \bar{n}$ the problem $\text{INVERSE}(P_i)$ is polynomial time reducible to the problem $\text{INVERSE}(P_\varphi)$.*

Proof. Let us prove statement (i1). Let $a = a_1 \cdots a_k$ be an element of A_φ . To find $P_\varphi(a)$ according to (14) we need to compute the words $P_\varphi(a_j)$, $j \in \bar{k}$, and then to compute the word \bar{w} where $w = P_\varphi(a_1) \cdots P_\varphi(a_k)$. The first stage can be done in time $|a|^{O(1)}$ because each mapping P_i , $i \in \bar{n}$, is polynomial time computable due to Section 2. Since the size of w equals $|a|$, the element $P_\varphi(a)$ can be found within the similar time bound (one should take into account that in the recursive procedure (6) applied for computing \bar{w} from w the length of a current word decreases at each step of the procedure).

To prove statements (i2) and (i3) we note first that the inclusion $\text{im}(P_\varphi) \subset \ker(\varphi)$ was proved after the definition of A_φ and P_φ in (14). The converse inclusion as well as statement (i3) will be proved by means of the following recursive procedure which for a given element $g = x_1 \cdots x_k$ of G with $x_j \in G_{i_j}$ for $j \in \bar{k}$, produces a certain pair $(a_g, t_g) \in A_\varphi \times G$. Below we show that this procedure actually solves the problem $\text{INVERSE}(P_\varphi)$.

Step 1. If $g = 1_G$, then output $(1_{A_\varphi}, 1_G)$.

Step 2. If the set $J = \{j \in \bar{k} : x_j \in \ker(f_{i_j})\}$ is empty, then output $(1_{A_\varphi}, g)$.

Step 3. Set $h = \overline{x_{j+1} \cdots x_k x_1 \cdots x_{j-1}}$ where j is the smallest element of the set J .

Step 4. Recursively find the pair (a_h, t_h) . If $t_h \neq 1_G$, then output (a_h, t_h) .

Step 5. If $t_h = 1_G$, then output $(a_g, 1_G)$ where $a_g = x_1 \cdots x_{j-1} a_j a_h x_{j-1}^{-1} \cdots x_1^{-1}$ with a_j being an arbitrary element of A_{i_j} such that $P_{i_j}(a_j) = x_j$. ■

Since each recursive call at Step 4 is applied to the word $h \in G$ of size at most $|g| - 1$, the number of recursive calls is at most $|g|$. So the total number of oracle Q_i calls, $i \in \bar{n}$, at Step 2 does not exceed $|g|^2$. Thus the running time of the algorithm is $(|g|)^{O(1)}$ and statements (i2), (i3) are consequences of the following lemma.

Lemma 3.3 $g \in \ker(\varphi)$ iff $t_g = 1_G$. Moreover, if $t_g = 1_G$, then $a_g \in A_\varphi$ and $P_\varphi(a_g) = g$.

Proof. We will prove the both statements by induction on $k = |g|$. If $k = 0$, then the procedure terminates at Step 1 and we are done. Suppose that $k > 0$. If the procedure terminates at Step 2, then $t_g \neq 1_G$. In this case we have $|\varphi(g)| = |g| = k > 0$, whence $g \notin \ker(\varphi)$. Let the procedure terminate at Step 4 or at Step 5. Then $|h| \leq |g| - 1$ (see Step 3). So by the induction hypothesis we can assume that $h \in \ker(\varphi)$ iff $t_h = 1_G$. On the other hand, taking into account that $x_j \in \ker(f_{i_j})$ (see the definition of j at Step 3) we get that $h \in \ker(\varphi)$ iff $\overline{u x_j h u^{-1}} \in \ker(\varphi)$ where $u = x_1 \dots, x_{j-1}$. Since

$$\overline{u x_j h u^{-1}} = \overline{x_1 \cdots x_{j-1} x_j h x_{j-1}^{-1} \cdots x_1^{-1}} = \overline{x_1 \cdots x_k} = \bar{g} = g, \quad (17)$$

this means that $g \in \ker(\varphi)$ iff $h \in \ker(\varphi)$ iff $t_h = 1_G$. This proves the first statement of the lemma because $t_h = t_g$ due to Steps 4 and 5.

To prove the second statement, suppose that $t_g = 1_G$. Then the above argument shows that $h \in \ker(\varphi)$ and so $a_h \in A_\varphi$ and $P_\varphi(a_h) = h$ by the induction hypothesis. This implies that $1_{A_\varphi} \rightarrow a_h$. On the other hand, from the definition of a_g at Step 5 it follows that $a_h \rightarrow a_g$ (see (13)). Thus $1_{A_\varphi} \rightarrow a_g$, i.e. $a_g \in A_\varphi$ (see (14)). Besides, from the minimality of j it follows that $x_l \in X$ (see (12)) and hence $P_\varphi(x_l) = x_l$ and $P_\varphi(x_l^{-1}) = x_l^{-1}$ for all $l \in \bar{j-1}$ (see (14)). Since $P_\varphi(a_j) = x_j$ and $\bar{h} = h = \overline{x_{j+1} \cdots x_k x_1 \cdots x_{j-1}}$ (see Step 3), we obtain by (17) that

$$P_\varphi(a_g) = \overline{u x_j P_\varphi(a_h) u^{-1}} = \overline{u x_j h u^{-1}} = g$$

which completes the proof of the Lemma 3.3. ■

To prove statement (i4) let $i \in \bar{n}$ and $g \in G_i$. Then since obviously $g \in \ker(f_i)$ iff $g \in \ker(\varphi)$, one can test whether $g \in \ker(f_i)$ by means of an algorithm solving the

problem $\text{INVERSE}(P_\varphi)$. Moreover, if $g \in \ker(f_i)$, then this algorithm yields an element $a \in A_\varphi$ such that $P_\varphi(a) = g$. Then assuming $a = a_1 \cdots a_k$ with $a_j \in X_\varphi$, the set $J_a = \{j \in \bar{k} : a_j =]a_j^*, i[\}$ can be found in time $O(|a|)$ (we recall that due to our presentation any element a_j is of the form either $]a_j^*, i_j[$ or $[a_j^*, i_j]$ where $i_j \in \bar{n}$ and $a_j^* \in \mathbb{Z}_{n_{i_j}}^*$, and $P_{i_j}(a_j) \in \ker(f_{i_j})$ iff $a_j \in A_0$ iff $a_j =]a_j^*, i_j[$). Now the element

$$a^* =] \prod_{j \in J_a} a_j^*, i[$$

obviously belongs to the set $A_i \subset A_0$. On the other hand, since $g \in G_i$, we get by (7) that

$$g = \overline{P_\varphi(a_1) \cdots P_\varphi(a_k)} = \overline{\prod_{j \in J} P_\varphi(a_j)} \quad (18)$$

where $J = \{j \in \bar{k} : P_\varphi(a_j) \in G_i\}$. Taking into account that G_i is an Abelian group and the mapping $P_i : A_i \rightarrow G_i$ is a homomorphism, we have

$$\overline{\prod_{j \in J} P_\varphi(a_j)} = \overline{\prod_{j \in J_a} P_i(a_j) \prod_{j \in J \setminus J_a} P_\varphi(a_j)} = \overline{P_i(a^*) \prod_{j \in J \setminus J_a} P_\varphi(a_j)}. \quad (19)$$

Moreover, since $1_{A_\varphi} \rightarrow a$, from (13) it follows that there exists involution $j \rightarrow j'$ on the set $J \setminus J_a$ such that $a_j =]a_j^*, i[$ iff $a_{j'} = [(a_j^*)^{-1}, i]$ (we recall that $a_j =]a_j^*, i[$ for $j \in J_a$ and $a_j = [a_j^*, i]$ for $j \in J \setminus J_a$). This implies that $\prod_{j \in J \setminus J_a} P_\varphi(a_j) = 1_G$. Thus from (18) and (19) we conclude that:

$$g = \overline{P_i(a^*)} = \overline{P_\varphi(a^*)} = P_\varphi(a^*).$$

This shows that the element $a^* \in A_i$ with $P_\varphi(a^*) = g$ can be constructed from a in time $O(|a|)$. Using condition (H1) for the cryptosystem \mathcal{S}_i , one can efficiently transform the element a^* to a random element \tilde{a} so that $P_\varphi(\tilde{a}) = P_\varphi(a^*) = g$. Thus the problem $\text{INVERSE}(P_i)$ is polynomial time reducible to the problem $\text{INVERSE}(P_\varphi)$. The Lemma 3.2 is proved. ■

Lemma 3.4 *Let K be the group given by presentation (9) and the epimorphism ψ is defined by (10). Then given $k \in K$ one can find the element $\psi(k)$ in time $(|k||H|)^{O(1)}$.*

Proof. It is easy to see that the group K can be identified with the subset of the set $W_{H\#}$ so that $w \in K$ iff the length of any subword of w of the form $h \cdots h$ (i.e. the repetition of a letter h) is at most $m_h - 1$. Having this in mind we claim that the following recursive procedure computes $\psi(k)$ for all $k = x_1 \cdots x_t \in K$.

Step 1. If $t \leq 1$, then output $\psi(k) = k$.

Step 2. Choose $h \in H$ such that $x_1 x_2 h \in \mathcal{R}^{(1)} \cup \mathcal{R}^{(2)}$.

Step 3. Output $\psi(k) = \psi(h^{-1} x_3 \cdots x_t)$.

The correctness of the procedure follows from the definitions of sets $\mathcal{R}^{(1)}$, $\mathcal{R}^{(2)}$, and the fact that recursion at Step 3 is always applied to a word the length of which is smaller than the length of the current word. In fact, the above procedure produces the representation of k in the form $k = w_1 \cdots w_{t-1} \psi(k)$ where $w_j \in \mathcal{R}^{(1)} \cup \mathcal{R}^{(2)}$ for all $j \in \overline{t-1}$ and $\psi(k) \in H$. Since obviously $w_1 \cdots w_{t-1} \in \ker(\psi)$, we conclude that $\psi(k) = h_k$ (see (10)). To complete the proof it suffices to note that the running time of the above procedure is $O(|k|(|\mathcal{R}^{(1)}| + |\mathcal{R}^{(2)}|))$. ■

Finally, let us complete the proof of Theorem 1.3. First, we observe that by Lemma 3.1 the mapping $f : G \rightarrow H$ is a composition of two epimorphisms and so is an epimorphism too. Next, to prove that the mapping $P : A \rightarrow \ker(f)$ is a surjection, we recall that the set R_φ defined after (15) is a right transversal of $\ker(\varphi)$ in G . So given $g \in \ker(f)$ there exist uniquely determined elements $g_\varphi \in \ker(\varphi)$ and $r_\varphi \in R_\varphi$ such that $g = \overline{g_\varphi r_\varphi}$. Since

$$1_H = f(g) = \psi(\varphi(\overline{g_\varphi r_\varphi})) = \psi(\varphi(r_\varphi)) = f(r_\varphi),$$

we see that $r_\varphi \in A_\psi$ (see 15). Besides, from statement (i2) of Lemma 3.2 it follows that there exists $a \in A_\varphi$ for which $P_\varphi(a) = g_\varphi$. Therefore, due to (16) we have

$$P(a, r_\varphi) = \overline{P_\varphi(a) P_\psi(r_\varphi)} = \overline{g_\varphi r_\varphi} = g.$$

Thus the mapping P is a surjection. Since conditions (H1)-(H3) of the Definition 1.1 are satisfied (see the end of Subsection 3.2), it remains to verify the condition (H4), i. e. that P is a trapdoor function.

First, we observe that by statement (i1) of Lemma 3.2 and by Lemma 3.4 the mappings P_φ and P_ψ are polynomial time computable, whence so does the mapping P . Next, given an element $g \in G$ there exists the uniquely determined element $r \in R$ such that $f(g) = f(r)$ or, equivalently, $f(gr^{-1}) = 1_H$. Since $|R| = O(1)$, this implies that the problem of the computation of the epimorphism f is polynomial time equivalent to the problem of recognizing elements of $\ker(f)$ in G , i. e. in our setting to the problem INVERSE(P). Thus, we have to show that

- (a) the problem INVERSE(P) can be efficiently solved by means of using the trapdoor information for the homomorphic cryptosystems (R_i, A_i, P_i) , $i \in \overline{n}$, i.e. the factoring of integers $n_i \in D_{n, m_i}$,
- (b) for any $i \in \overline{n}$ the problem INVERSE(P_i) (to which the factoring of integers n_i is reduced) is polynomial time reducible to the problem INVERSE(P).

Suppose that for each $i \in \bar{n}$ there is an oracle for the problem $\text{INVERSE}(P_i)$. Then given $g_i \in G_i$ one can find the element $f_i(g_i)$ in time $N^{O(1)}$. So given $g \in G$ the element $k = \varphi(g)$ can be found in time $(|g|N)^{O(1)}$ (see (8)). Since $f(g) = \psi(\varphi(g)) = \psi(k)$ and $|k| \leq |g|$, one can find $\psi(k)$ by Lemma 3.4 and then to test whether $g \in \ker(f)$ within the same time. Moreover, due to condition (H3) for cryptosystems \mathcal{S}_i , $i \in \bar{n}$, one can efficiently find an element r belonging to the right transversal R_φ of $\ker(\varphi)$ in G such that $\varphi(r) = k$ and $|r| \leq |k|$. Now if $g \in \ker(f)$ then $\psi(k) = 1_H$ and so $r \in A_\psi$. Furthermore,

$$\varphi(gr^{-1}) = \varphi(g)\varphi(r^{-1}) = kk^{-1} = 1_K.$$

Finally, from statement (i3) of Lemma 3.2 it follows that one can find in time $(|g|N)^{O(1)}$ an element $a \in A_\varphi$ such that $P_\varphi(a) = gr^{-1}$. Thus we obtain

$$P(a, r) = \overline{P_\varphi(a)P_\psi(r)} = \overline{gr^{-1}r} = \bar{g} = g,$$

which proves claim (a).

To prove claim (b) let $g \in G$. If $g \notin \ker(f)$, then obviously $g \notin \ker(\varphi)$. Let now $g \in \ker(f)$ and $(a, b) \in A$ be such that $\overline{P_\varphi(a)P_\psi(b)} = g$. Since $P_\psi(b)$ belongs to the right transversal R_φ of $\ker(\varphi)$ in G , it follows that $g \in \ker(\varphi)$ iff $P_\psi(b) = 1_G$. Moreover, if $P_\psi(b) = 1_G$, then obviously $P_\varphi(a) = g$. Taking into account that the element $P_\psi(b)$ can be found in time $|b|^{O(1)}$ (see (15)), we conclude that the problem $\text{INVERSE}(P_\varphi)$ is polynomial time reducible to the problem $\text{INVERSE}(P)$. Thus claim (b) follows from statement (i4) of Lemma 3.2. Theorem 1.3 is proved. ■

4 Encrypted simulating of boolean circuits

Let $B = B(X_1, \dots, X_n)$ be a boolean circuit and H be a group. Following [1] we say that a word

$$h_1^{X_{l_1}} \dots h_m^{X_{l_m}}, \quad h_1, \dots, h_m \in H, \quad l_1, \dots, l_m \in \bar{n}, \quad (20)$$

is a *simulation* of size m of B in H if there exists a certain element $h \in H^\#$ such that the equality

$$h_1^{x_{l_1}} \dots h_m^{x_{l_m}} = h^{B(x_1, \dots, x_n)}$$

holds for any boolean vector $(x_1, \dots, x_n) \in \{0, 1\}^n$. It is proved in [1] that given an arbitrary *unsolvable* group H and a boolean circuit B there exists a simulation of B in H , the size of this simulation is exponential in the depth of B (in particular, when the depth of B is logarithmic $O(\log n)$, then the size of the simulation is $n^{O(1)}$).

We say that the circuit B is *encrypted simulated* over a homomorphic cryptosystem with respect to an epimorphism $f : G \rightarrow H$ (we use the notations from Definition 1.1) if there exist $g_1, \dots, g_m \in G$, and a certain element $h \in H^\#$ such that

$$f(g_1^{x_{l_1}} \dots g_m^{x_{l_m}}) = h^{B(x_1, \dots, x_n)} \quad (21)$$

for any boolean vector $(x_1, \dots, x_n) \in \{0, 1\}^n$. Thus having a simulation (20) of the circuit B in H one can produce an encrypted simulation of B by choosing randomly $g_i \in G$ such that $f(g_i) = h_i, i \in \overline{m}$ (in this case, equality (21) is obvious). Now combining Theorem 1.3 with the above mentioned result from [1] we get the following statement.

Corollary 4.1 *For an arbitrary finite unsolvable group H , a homomorphic cryptosystem \mathcal{S} of a size N over H and any boolean circuit of the logarithmic depth $O(\log N)$ one can design in time $N^{O(1)}$ an encrypted simulation of this circuit over \mathcal{S} . ■*

The meaning of an encrypted simulation is that given (publically) the elements $g_1, \dots, g_m \in G$ and $h \in H^\#$ from (21) it should be supposedly difficult to evaluate $B(x_1, \dots, x_n)$ since for this purpose one has to verify whether an element $g_1^{x_{l_1}} \cdots g_m^{x_{l_m}}$ belongs to $\ker(f)$. On the other hand, the latter can be performed using the trapdoor information. In conclusion let us mention the following two known schemes of interaction (cf. e.g. [2, 24, 21, 22]) based on encrypted simulations.

The first scheme is called *evaluating an encrypted circuit*. Assume that Alice knows a trapdoor in a homomorphic cryptosystem over a group H with respect to an epimorphism $f : G \rightarrow H$ and possesses a boolean circuit B which she prefers to keep secret, and Bob wants to evaluate $B(x)$ at an input $x = (x_1, \dots, x_n)$ (without knowing B and without disclosing x). To accomplish this Alice transmits to Bob an encrypted simulation (21) of B , then Bob calculates the element $g = g_1^{x_{l_1}} \cdots g_m^{x_{l_m}}$ and sends it back to Alice, who computes and communicates the value $f(g)$ to Bob.

In a different setting one could consider in a similar way evaluating an encrypted circuit $B_H(y_1, \dots, y_n)$ over a group H (rather than a boolean one), being a sequence of group operations in H with inputs $y_1, \dots, y_n \in H$. The second (dual) scheme is called *evaluating at an encrypted input*. Now Alice has an input $y = (y_1, \dots, y_n)$ (desiring to conceal it) which she encrypts randomly by the tuple $z = (z_1, \dots, z_n)$ belonging to G^n such that $f(z_i) = y_i, i \in \overline{n}$, and transmits z to Bob. In his turn, Bob who knows a circuit B_H (which he wants to keep secret) yields its “lifting” $f^{-1}(B_H)$ to G by means of replacing every constant $h \in H$ occurring in B_H by any $g \in G$ such that $f(g) = h$ and replacing the group operations in H by the group operations in G , respectively. Then Bob evaluates the element $(f^{-1}(B_H))(z) \in G$ and sends it back to Alice, finally Alice applies f and obtains $f((f^{-1}(B_H))(z)) = B_H(y)$ (even without revealing it to Bob).

It would be interesting to design homomorphic cryptosystems over *rings* rather than groups.

Acknowledgements. The authors would like to thank the Max-Planck Institut fuer Mathematik (Bonn) during the stay in which this paper was initiated; also Igor Shparlinski for useful discussions. The research of the second author was supported by grant of NATO.
