#### Abstract

PC(l) of order k is one of the most general cryptographic criteria of secure Boolean functions. In this paper, we introduce its  $\epsilon$ -almost version. The new definition requires *only* that  $f(X) + f(X + \Delta)$  is *almost* uniformly distiributed (while the original definition of PC(l) of order k requires that it is *strictly* uniformly distiributed). We next show its construction. Better parameters are then obtained than normal PC(l) of order k functions.

(Keywords) Boolean functions, PC(l) of order k,  $\epsilon$ -almost version

# 1 Introduction

Several cryptographic criteria of Boolean functions have been studied by many researchers in order to design secure block ciphers. Among them, PC(l) of order k [15, 16] is one of the most general criteria.

A Boolean function f(X) satisfies PC(l) if the output difference  $f(X) + f(X + \Delta)$  is uniformly distributed for any input difference  $\Delta$  such that the Hamming weight  $\Delta$  is equal to l or less. (That is,  $1 \leq wt(\Delta) \leq l$ , where  $wt(\Delta)$  denotes the Hamming weight of  $\Delta$ .) Further suppose that f(X) satisfies PC(l) even if any k bits of  $X = (x_1, \dots, x_n)$  are fixed into any constants. Then we say that f(X) satisfies PC(l) of order k.

The famous strict avalanche criterion (SAC), which was introduced as a criterion of the security of S-boxes [17], is equivalent to PC(1). SAC(k) is

equivalent to PC(1) of order k. Also, f(X) is a bent function [10] if and only if f(X) satisfies PC(n) [15], where a bent function has the largest distance from the set of affine (linear) functions. (Hence it is directly related to the linear attack.) PC(l) of order k in general is directly related to the security against differential attacks.

Kurosawa et al. gave a general method to design such functions by using linear codes [9]. Carlet extended it to nonlinear codes [4].

Boolean functions, however, do not need to satisfy the strict definitions of cryptographic criteria in general. These definitions are sometimes stronger than what we want, *i.e.*, attacks on block ciphers should be impossible. (It is well-known that bent functions cannot be balanced.) Therefore, as far as attacks are impossible, it will be better if better parameters are obtained by relaxing the definitions.

From this point of view, this paper intoduces a notion of  $\epsilon$ -almost PC(l) of order k. It requires ony that  $f(X) + f(X + \Delta)$  is almost uniformly distiributed in the original definition of PC(l) of order k. We then show that indeed better parameters are obtained than normal PC(l) of order k functions.

We present a design method of  $\epsilon$ -almost PC(l) of order k functions using linear codes and a  $\epsilon$ -biased sample spaces [11] which satisfy some property. Our construction offers smaller input length n than normal PC(l) of order k functions for the same (l, k). (The input size n of Sboxes can be smaller for the security level (l, k).) In other words, we can obtain larger (l, k) for the same input length n. (Higher security level (l, k) can be obtained for the same input size n of Sboxes.) We further generalize our result to multiple output bits Boolean functions.

Related works: Suppose that  $F(x_1, \dots, x_n) = (y_1, \dots, y_m)$  is uniformly distributed even if any k bits of  $(x_1, \dots, x_n)$  are fixed into any constants. We then say that F is an (n, m, k)-resilient function. This notion has been studied by several researchers from a view point of key renewal [5, 2, 7, 13, 3, 14]. Especially, [8] introduced a notion of  $\epsilon$ -almost k-resilient functions. The authors presented its construction and showed that better parameters are obtained than normal k-resilient functions. Dodis et al. improved it by showing a probabilistic construction [6].

Our work can be considered as an extension of [8]. Indeed, we show that an  $\epsilon$ -almost PC(l) of order k function is obtained from a linear code and an  $\epsilon$ -almost k-resilient function which satisfies some special property. However, we cannot use the previous constructions of  $\epsilon$ -almost k-resilient functions [8, 6] because it is not known if they satisfy our special property.

# 2 Preliminaries

 $wt(\Delta)$  denotes the Hamming weight of a binary vector  $\Delta$ . Let  $\cdot$  denote the inner product of two binary vectors over GF(2). For a set A, |A| denotes the cardinality of A.

Let a linear [N, m, d]-code denote a binary linear code C of length N, dimension m and the minimum Hamming distance at least d. The dual code  $C^{\perp}$  of a linear code C is defined as  $C^{\perp} \stackrel{\triangle}{=} \{u \mid u \cdot v = 0 \text{ for all } v \in C\}$ . The dual minimum Hamming distance  $d^{\perp}$  of C is defined as the minimum Hamming distance of  $C^{\perp}$ .

#### 2.1 Resilient Functions

**Definition 2.1** We say that  $F(X) = (y_1, \dots, y_m)$  is a (n, m, k)-resilient function if F(X) is uniformly distributed even if any k variables  $x_{i_1}, \dots, x_{i_k}$  are fixed into any constants. That is,

$$\Pr[f(x_1, \dots, x_n) = (y_1, \dots, y_m) \mid x_{i_1} x_{i_2} \cdots x_{i_k} = \alpha] = 2^{-m}$$

for any k positions  $i_1 < \cdots < i_k$ , for any k-bit string  $\alpha \in \{0,1\}^k$  and for any  $(y_1, \cdots, y_m) \in \{0,1\}^l$ , where the values  $x_j$   $(j \notin \{i_1, \ldots, i_k\})$  are chosen independently at random.

Chor et al. showed that a (n, m, k)-resilient function can be obtained from a linear [n, m, k + 1]-code [5].

**Proposition 2.1** Let G be a generator matrix of a linear [n, m, k+1]-code C. Then  $F(X) = G \cdot X$  is a (n, m, k)-resilient function.

(Proof) It is known that  $F(X) = (y_1, \dots, y_m)$  is a (n, m, k)-resilient function if and only if

$$a_1y_1 + \dots + a_m y_m \tag{1}$$

is a (n, 1, k)-resilient function for any  $(a_1, \dots, a_m) \neq (0, \dots, 0)$ . (See [5].) In our case, eq.(1) becomes as follows.

$$(a_1, \cdots, a_m) \cdot GX = (b_1, \cdots, b_n) \cdot X,$$

where  $(b_1, \dots, b_n) = (a_1, \dots, a_m) \cdot G$ . Note that  $wt(b_1, \dots, b_n) \ge k + 1$  because  $(b_1, \dots, b_n)$  is a nonzero codeword of C. Then it is easy to see that  $(b_1, \dots, b_n) \cdot X$  is k-resilient.

Q.E.D.

#### **2.2** PC(l) of order k

**Definition 2.2** [15, 16] We say that f(X) satisfies PC(l) of order k if  $f(X) + f(X + \Delta)$  is k-resilient for any  $\Delta$  such that  $1 \le wt(\Delta) \le l$ . (We also say that f(X) is a PC(l) of order k function.)

Kurosawa et al. gave a general method to design PC(l) of order k functions by using two linear codes [9].

**Proposition 2.2** Suppose that there exist

- 1. a linear  $[n_1, m, k+1]$ -code  $C_1$  with the dual minimum Hamming distance at least l+1 and
- 2. a linear  $[n_2, m, k+1]$ -code  $C_2$  with the dual minimum Hamming distance at least l+1.

Then there exists a a PC(l) of order k function  $f(x_1, \dots, x_n)$  such that

 $n = n_1 + n_2.$ 

# **3** Almost Resilient Functions

In [8], the authors introduced a notion of *almost* resilient functions and showed its construction. Then better parameters are obtained than normal resilient functions.

# 3.1 Almost k-Wise Independent Sample Space

Let  $S_n \subseteq \{0,1\}^n$ . We consider that  $S_n$  is a  $|S_n| \times n$  binary matrix and each row is randomly chosen.

**Definition 3.1**  $S_n$  is  $\epsilon$ -biased if

$$\left|\Pr_{X\in S_n}(X\cdot\alpha=0) - \Pr_{X\in S_n}(X\cdot\alpha=1)\right| \le \epsilon$$

for any  $\alpha \in \{0,1\}^n \setminus \{0^n\}$ .

**Definition 3.2** (almost k-wise independence). Suppose that  $X = x_1 \cdots x_N$  is chosen randomly from  $S_N$ . Then we say that  $S_N$  is  $(\epsilon, k)$ -independent if for any k positions  $i_1 < i_2 < \cdots < i_k$  and any k-bit string  $\alpha$ , we have

$$\left|\Pr[x_{i_1}x_{i_2}\cdots x_{i_k}=\alpha]-2^{-k}\right| \le \epsilon.$$

**Proposition 3.1** [11] Suppose that  $S_n$  is  $\epsilon$ -biased. Let H be a parity check matrix of a [N, N - n, k + 1]-linear code C. Define

$$S_N \stackrel{\triangle}{=} S_n \cdot H$$

Then  $S_N$  is  $(\tilde{\epsilon}, k)$ -independent, where

$$\widetilde{\epsilon} = \left(1 - \frac{1}{2^k}\right) \cdot \epsilon$$

#### 3.2 Almost Resilient Functions

**Definition 3.3** [8] The function f(X) is called an  $\epsilon$ -almost (n, m, k)-resilient function if

$$|\Pr[f(x_1,...,x_n) = (y_1,...,y_m) | x_{i_1}x_{i_2}\cdots x_{i_k} = \alpha] - 2^{-m}| \le \epsilon$$

for any k positions  $i_1 < \cdots < i_k$ , for any k-bit string  $\alpha \in \{0,1\}^k$  and for any  $(y_1, \cdots, y_m) \in \{0,1\}^m$ , where the values  $x_j$   $(j \notin \{i_1, \ldots, i_k\})$  are chosen independently at random.

**Definition 3.4** [8] An  $(\epsilon, k)$ -independent sample space  $S_N$  is called *t*-systematic if  $|S_N| = 2^t$ , and there exist *t* positions  $i_1 < \cdots < i_t$  such that each *t*-bit string occurs in these positions for exactly one *N*-tuple in  $S_N$ .

We define *t*-systematic  $\epsilon$ -biased sample spaces similarly.

**Proposition 3.2** [8, Theorem 4.4] If there exists a t-systematic  $(\epsilon, k)$ -independent sample space  $S_N$ , then there exists a balanced  $\delta$ -almost (N, N-t, k)-resilient function, where  $\delta = \epsilon/2^{N-t-k}$ .

The  $\delta$ -almost (N, N - t, k)-resilient function given in Proposition 3.2 is constructed as follows [8]. Without loss of generality, assume that the first tpositions in  $S_N$  run through all possible t-bit strings. We then obtain  $2^{N-t}$ sample spaces  $E_{\alpha}$  indexed by  $\alpha = (\alpha_1, \ldots, \alpha_{N-t}) \in \{0, 1\}^{N-t}$  by

$$E_{\alpha} = S_N + (\underbrace{0, 0, \dots, 0}_{t}, \alpha_1, \dots, \alpha_{N-t}).$$

Finally define a function  $\phi : \{0,1\}^N \to \{0,1\}^{N-t}$  by the rule

$$\phi(x_1,\ldots,x_m) = \alpha$$
 if and only if  $(x_1,\ldots,x_N) \in E_{\alpha}$ .

Then  $\phi$  is a  $\delta$ -almost (N, N - t, k)-resilient function, where  $\delta$  is given in Proposition 3.2.

# 4 Almost PC(l) of order k

In this section, we introduce a notion of almost PC(l) of order k functions. We then show that an almost PC(l) of order k function is obtained from a linear code and an  $\epsilon$ -almost (n, m, k)-resilient function which satisfies some property.

**Definition 4.1** We say that f(X) satisfies  $\epsilon$ -almost PC(l) of order k if  $f(X) + f(X + \Delta)$  is an  $\epsilon$ -almost (n, 1, k)-resilient function for any  $\Delta$  such that  $1 \leq wt(\Delta) \leq l$ . (We also say that f(X) is an  $\epsilon$ -almost PC(l) of order k function.)

### 4.1 Basic Theorem

**Definition 4.2** For  $\Phi : \{0,1\}^n \to \{0,1\}^m$ , we define the domain distance  $d_{\Phi}$  as follows. Suppose that

$$\Phi(\beta) \neq \Phi(\beta + \Omega)$$

for any  $\beta$  and any  $\Omega$  such that  $1 \leq wt(\Omega) \leq l$ . Then  $d_{\Phi} \geq l+1$ .

**Lemma 4.1** Let  $\phi(X) = (y_1, \dots, y_m)$  be an  $\epsilon$ -almost (n, m, k)-resilient function. Then  $\phi(X) \cdot \Delta$  is a  $(2^{m-1}\epsilon)$ -almost (n, 1, k)-resilient function for any  $\Delta \neq (0, \dots, 0)$ .

(Proof) For any  $\Delta \neq (0, \dots, 0)$ , let

$$A_0 = \{ Y \mid Y \cdot \Delta = 0 \}, \ A_1 = \{ Y \mid Y \cdot \Delta = 1 \}.$$

Then  $|A_0| = |A_1| = 2^{m-1}$ . Therefore,

$$\Pr(\phi(X) \cdot \Delta = 0) = \sum_{\alpha \in A_0} \Pr(\phi(X) = \alpha) \ge \sum_{\alpha \in A_0} (2^{-m} - \epsilon) = 1/2 - 2^{m-1}\epsilon.$$

Similarly we have

$$\Pr(\phi(X) \cdot \Delta = 0) \le 1/2 + 2^{m-1}\epsilon.$$

Hence

$$|\Pr(\phi(X) \cdot \Delta = 0) - 1/2| \le 2^{m-1}\epsilon.$$

Similarly,

$$|\Pr(\phi(X) \cdot \Delta = 1) - 1/2| \le 2^{m-1}\epsilon$$

Q.E.D.

Then our basic theorem is stated as follows.

#### **Theorem 4.1** Suppose that there exist

- 1. a linear  $[n_1, m, k+1]$ -code  $C_1$  with the dual minimum Hamming distance at least l+1 and
- 2. an  $\epsilon$ -almost  $(n_2, m, k)$ -resilient function  $\Phi$  with the domain distance  $d_{\Phi} \geq l+1$ .

Then there exists a  $(2^{m-1}\epsilon)$ -almost PC(l) of order k function  $f(x_1, \dots, x_n)$  such that

$$n = n_1 + n_2$$

(Proof) Let  $G_1$  be a generator matrix of  $C_1$ . For  $X = (x_1, \dots, x_{n_1})$  and  $Y = (y_1, \dots, y_{n_2})$ , define

$$f(X,Y) = \Phi(Y) \cdot G_1 X + g(Y),$$

where g(Y) is any Boolean function. We show that f(X, Y) satisfies  $(2^{m-1}\epsilon)$ -almost PC(l) of order k. Let

$$f'(X,Y) = f(X,Y) + f(X + \Delta, Y + \Omega),$$

then

$$f'(X,Y) = (\Phi(Y) + \Phi(Y + \Omega)) \cdot G_1 X + \Phi(Y + \Omega) \cdot G_1 \Delta + g(Y) + g(Y + \Omega)$$

**Case 1.** Suppose that  $\Omega = 0$  and  $1 \le wt(\Delta) \le l$ . In this case,

$$f'(X,Y) = \Phi(Y) \cdot G_1 \Delta.$$

Then  $G_1\Delta \neq \mathcal{O}$  because  $\Delta$  is not a codeword of  $C_1^{\perp}$ . Hence f'(X, Y) is  $(2^{m-1}\epsilon)$ -almost k-resilient from Lemma 4.1.

**Case 2.** Suppose that  $\Omega \neq 0$  and  $1 \leq wt(\Delta) + wt(\Omega) \leq l$ . Then for any  $\beta$ ,

$$f'(X,\beta) = (\Phi(\beta) + \Phi(\beta + \Omega)) \cdot G_1 X + \gamma,$$

where  $\gamma = \Phi(\beta + \Omega) \cdot G_1 \Delta + g(\beta) + g(\beta + \Omega)$  is a constant. Now  $\Phi(\beta) \neq \Phi(\beta + \Omega)$  because  $d_{\Phi} \geq l + 1$ . Therefore,  $f'(X, \beta)$  is k-resilient from the proof of Proposition 2.1.

This means that f'(X, Y) is k-resilient.

Consequently, f(X, Y) satisfies  $2^m \epsilon$ -almost PC(l) of order k. Q.E.D.

**Remark 4.1** Kurosawa et al. [8] and Dodis et al. [6] showed how to construct  $\epsilon$ -almost (n, m, k)-resilient functions. However, it is not known if their constructions satisfy our condition on the *domain distance*.

#### 4.2 Discussion

Proposition 2.2 is obtained as a corollary of Theorem 4.1. Indeed, it is easy to show that if there exists a linear  $[n_2, m, k + 1]$ -code with the dual minimum Hamming distance at least l + 1, then there exists a  $(n_2, m, k)$ resilient function with the domain distance  $d_{\Phi} \geq l + 1$ .

Now suppose that there exists a linear  $[n_2, m, k+1]$ -code. In what follows, we show that there exists an  $\epsilon$ -almost  $(n'_2, m, k)$ -resilient function with the domain distance  $d_{\Phi} \geq l+1$  such that  $n'_2 < n_2$ .

This means that we can obtain smaller input length n for the same (l, k). In other words, we can obtain larger (l, k) for the same n.

# 5 Construction

#### 5.1 Overview

In this section, we show how to achieve the second condition of Theorem 4.1, i.e. how to construct an  $\epsilon$ -almost (n, m, k)-resilient function with a domain distance at least l + 1.

For a  $(\epsilon, k)$ -independent sample space  $S_N$ , we can consider a nonlinear code  $C(S_N)$  such that each row of  $S_N$  is a codeword.

**Definition 5.1** For  $S_N$ , let d be the minimum Hamming distance of  $C(S_N)$ . Then we say that  $S_N$  has the domain distance d.

- 1. We first show that the second condition of Theorem 4.1 is satisfied if there exists a *t*-systematic  $(\epsilon, k)$ -independent sample space  $S_N$  whose domain distance is at least l + 1.
- 2. We next show that such  $S_N$  is obtained from a *t*-systematic  $\epsilon$ -biased sample space  $S_n$  and a linear [N, N n, k + 1]-code with the dual minimu Hamming distance at least l + 1.
- 3. We finally show how to construct such  $S_n$  by using Weil-Carlitz-Uchiyama bound. (The same technique was used in [8] to construct a *t*-systematic  $(\epsilon, k)$ -independent sample space  $S_N$ .)

#### 5.2 General Construction

**Theorem 5.1** Suppose that there exists a t-systematic  $(\epsilon, k)$ -independent sample space  $S_N$  with the domain distance at least l+1. Then there exists a balanced  $\delta$ -almost (N, N-t, k)-resilient function  $\phi$  with the domain distance  $d_{\phi}$  at least l+1, where  $\delta = \epsilon/2^{N-t-k}$ .

(Proof) Construct  $\phi$  from  $S_N$  by using the method shown just after Proposition 3.2. Suppose that  $d_{\phi} \leq l$ . That is,  $\phi(\beta) = \phi(\beta + \Omega) = \alpha$  for some  $\alpha, \beta$  and  $\Omega$  such that  $1 \leq wt(\Omega) \leq l$ . Then we see that

$$\beta + (0, \dots, 0, \alpha) \in S_N$$
 and  $\beta + \Omega + (0, \dots, 0, \alpha) \in S_N$ .

This means that there are two codewords with the distance l or less in  $S_N$ . However, this is a contradiction because  $S_N$  has the domain distance at least l+1.

#### Q.E.D.

**Theorem 5.2** Suppose that there exists a t-systematic  $\epsilon$ -biased sample space  $S_n$  and a linear [N, N - n, k + 1]-code C with the dual minimum Hamming distance at least l + 1. Then there exists a t-systematic  $(\tilde{\epsilon}, k)$ -independent sample space  $S_N$  with the domain distance at least l + 1, where

$$\widetilde{\epsilon} = \left(1 - \frac{1}{2^k}\right) \cdot \epsilon.$$

(Proof) Let  $H = (I_n, \tilde{H})$  be a parity check matrix of C, where  $I_n$  is the  $n \times n$  identity matrix. Let

$$S_N = S_n \cdot H. \tag{2}$$

Then  $S_N$  is  $(\tilde{\epsilon}, k)$ -independent from Propposition 3.1, where

$$\widetilde{\epsilon} = \left(1 - \frac{1}{2^k}\right) \cdot \epsilon$$

Next it is easy to see that  $S_N$  is t-systematic if  $S_n$  is t-systematic. Finally, we show that  $S_N$  has the domain distance at least l+1. From eq.(2), we see that  $S_N$  is a subset of all codewords of  $C^{\perp}$ . Therefore  $S_N$  has the domain distance at least l+1 because C has the dual distance at least l+1. Q.E.D.

#### 5.3 Construction of Systematic $\epsilon$ -Biased Sample Space

We next show how to construct a *t*-systematic  $\epsilon$ -biased sample space  $S_n$  by using Weil-Carlitz-Uchiyama bound. For  $x \in GF(2^t)$ , let

$$\operatorname{Tr}(x) \stackrel{\triangle}{=} x + x^2 + x^{2^2} + \dots + x^{2^{t-1}}$$

It is well-known that  $\operatorname{Tr}(x) = 0$  or 1 and  $\operatorname{Tr}(x_1 + x_2) = \operatorname{Tr}(x_1) + \operatorname{Tr}(x_2)$ .

**Proposition 5.1** (Weil-Carlitz-Uchiyama Bound) [18, 10] Let  $f(x) = \sum_{i=1}^{D} f_i x^i \in GF(2^t)[x]$  be a polynomial such that  $f(x) \neq g(x)^2 - g(x) + \theta$  for any polynomial  $g(x) \in GF(2^t)[x]$  and for any constant  $\theta \in F_{2^t}$ . Then

$$\left|\sum_{\alpha \in GF(2^t)} (-1)^{\operatorname{Tr}(f(\alpha))}\right| \le (D-1)\sqrt{2^t}.$$

**Remark 5.1** It is easy to see that if f(x) is an odd degree polynomial, then  $f(x) \neq g(x)^2 - g(x) + \theta$  for any g(x) and any  $\theta$ .

Now for two positive integers t and D', let n = tD' and D = 2D' - 1, g be a primitive element of  $GF(2^t)$  and  $x_1, x_2, \dots, x_{2^t}$  be the elements of  $GF(2^t)$ . For each  $x_i \in GF(2^t)$ , let  $X_i$  be a string of length n = tD' such that

$$X_i \stackrel{\triangle}{=} (Z_{i,1}, Z_{i,2}, \cdots, Z_{i,D'}),$$

where

$$Z_{i,j} \stackrel{\triangle}{=} (\operatorname{Tr}(x_i^{2j-1}), \operatorname{Tr}(gx_i^{2j-1}), \cdots, \operatorname{Tr}(g^{t-1}x_i^{2j-1}))$$

The proposed  $\epsilon\text{-biased}$  sample space is defined as

$$S_n \stackrel{\bigtriangleup}{=} \{X_1, X_2, \cdots, X_{2^t}\}.$$

**Theorem 5.3** The above  $S_n \subseteq \{0,1\}^n$  is a t-systematic  $\epsilon$ -biased sample space such that  $n = tD', |S_n| = 2^t$  and

$$\epsilon = \frac{2(D'-1)}{\sqrt{2^t}}.$$

(Proof) First it is a well known fact [8, page 245] that

$$Y_x = (Tr(x), Tr(gx), \dots, Tr(g^{t-1}x))$$

runs through  $\{0,1\}^t$  when x runs through  $GF(2^t)$ . Hence  $S_n$  is t-systematic. Next consider  $\alpha \in \{0,1\}^n \setminus \{0^n\}$ . Let  $\alpha = (\Lambda_1, \Lambda_2, \cdots, \Lambda_{D'})$  with

$$\Lambda_j = (\alpha_{0,2j-1}, \alpha_{1,2j-1}, \cdots, \alpha_{t-1,2j-1}).$$

Then since  $\alpha_{i,j}$  is binary, we have that

$$X_{i} \cdot \alpha = \sum_{j=1}^{D'} (\alpha_{0,2j-1} \operatorname{Tr}(x_{i}^{2j-1}) + \dots + \alpha_{t-1,2j-1} \operatorname{Tr}(g^{t-1}x_{i}^{2j-1}))$$
  
$$= \sum_{j=1}^{D'} \operatorname{Tr}(\alpha_{0,2j-1} + \alpha_{1,2j-1}g + \dots + \alpha_{t-1,2j-1}g^{t-1})x_{i}^{2j-1}))$$
  
$$= \operatorname{Tr}(a_{1}x_{j} + a_{3}x_{i}^{3} + \dots + a_{D}x_{i}^{D}), \qquad (3)$$

where

$$a_j \stackrel{\Delta}{=} \alpha_{0,j} + \alpha_{1,j}g + \dots + \alpha_{t-1,j}g^{t-1}$$

Since g is a primitive element,  $a_j = 0$  if an only if  $(\alpha_{0,j}, \alpha_{1,j}, \dots, \alpha_{t-1,j}) = (0, \dots, 0)$ . This implies that  $(a_1, \dots, a_D) \neq (0, \dots, 0)$  because  $\alpha \neq 0$ .

Now define

$$f_i(x) \stackrel{\triangle}{=} a_1 x_i + a_3 x_i^3 + \dots + a_D x_i^D$$

Let

$$A_0 \stackrel{\triangle}{=} \{x_i | \operatorname{Tr}(f(x_i)) = 0\}, \ A_1 \stackrel{\triangle}{=} \{x_i | \operatorname{Tr}(f(x_i)) = 1\}.$$

Then we see that

$$|\Pr(X \cdot \alpha = 0) - \Pr(X \cdot \alpha = 1)| = \left| \frac{|A_0|}{2^t} - \frac{|A_1|}{2^t} \right| \\ = \frac{1}{2^t} \left| \sum_{x_i \in GF(2^t)} (-1)^{\operatorname{Tr}(f(x_i))} \right|.$$

Finally from Weil-Carlitz-Uchiyama bound (see Remark 5.1, too), we have

$$|\Pr(X \cdot \alpha = 0) - \Pr(X \cdot \alpha = 1)| \le \frac{(D-1)\sqrt{2^t}}{2^t} = \frac{D-1}{\sqrt{2^t}}$$

Hence

$$\epsilon = \frac{D-1}{\sqrt{2^t}} = \frac{2(D'-1)}{2^{t/2}}.$$
 Q.E.D.

#### 5.4 Final Result

**Corollary 5.1** Suppose there exists a [N, N-tD', k+1]-code C with the dual distance at least l + 1. Then there exists a balanced  $\delta$ -almost (N, N - t, k)-resilient function with the domain distance at least l + 1 such that

$$\delta = \left(1 - \frac{1}{2^k}\right) \frac{2(D' - 1)\sqrt{2^t}}{2^{N-k}}.$$

(Proof) From Theorem 5.1, 5.2 and 5.3.

Q.E.D.

From Theorem 4.1 and Corollary 5.1, we finally obtain the following corollary.

#### **Corollary 5.2** Suppose that there exist

- 1. a linear  $[n'_1, m, k + 1]$ -code  $C'_1$  with the dual minimum Hamming distance at least l + 1 and
- 2. a linear  $[n'_2, m (D' 1)t, k + 1]$ -code  $C'_2$  with the dual minimum Hamming distance at least l + 1

Then there exists a  $(2^{m-1}\delta)$ -almost PC(l) of order k function  $f(x_1, \dots, x_n)$  such that

$$n' = n_1' + n_2',$$

where

$$\delta = \left(1 - \frac{1}{2^k}\right) \frac{2(D' - 1)\sqrt{2^t}}{2^{N-k}}.$$

# 6 Comparison

Let's compare the parameters of our construction (Corollary 5.2) with normal PC(l) of order k functions (Proposition 2.2).

We first show that our construction has a smaller input length than normal PC(l) of order k functions for the same (l, k). Let n' denote the input length of our construction and n denote the input length of Proposition 2.2. We use  $C'_1, C'_2$  to refer the linear codes of Corollary 5.2 and  $C_1, C_2$  to refer the linear codes of Proposition 2.2, respectively. Suppose that

- 1.  $C_1 = C'_1$  (hence  $n_1 = n'_1$ ).
- 2. Each of  $C_2$  and  $C'_2$  has the minimum Hamming distances at least k+1 and the dual minimum Hamming distances at least l+1.

Then

the dimension of 
$$C'_2 = m - (D'-1)t$$
,  
the dimension of  $C_2 = m$ 

Therefore,  $n'_2 < n_2$  because m - (D' - 1)t < m. Hence

n' < n.

This shows that our construction has a smaller input length for the same (l, k).

In other words, we can say that our construction has larger (l, k) for the same input length n.

# 7 Generalization to Multiple Output Bits

In this section, we generalize our result to multiple output Boolean functions.

**Definition 7.1** We say that  $F(X) = (f_1, \dots, f_p)$  satisfies  $\epsilon$ -almost PC(l)of order k if  $a_1f_1 + \dots + a_pf_p$  satisfies  $\epsilon$ -almost PC(l) of order k for any  $(a_1, \dots, a_p) \neq (0, \dots, 0).$ 

Theorem 7.1 Suppose that there exist

1. a linear  $[n_1, m, k + 1]$ -code  $C_1$  with the dual minimum Hamming distance at least l + 1 and 2. a linear  $[n_2, m - (D' - 1)t, k + 1]$ -code  $C_2$  with the dual minimum Hamming distance at least l + 1

Then there exists a  $(2^{m-1}\delta)$ -almost PC(l) of order k function  $F(x_1, \dots, x_n) = (y_1, \dots, y_m)$  such that  $n = n_1 + n_2$ , where

$$\delta = \left(1 - \frac{1}{2^k}\right) \frac{2(D' - 1)\sqrt{2^t}}{2^{N-k}}.$$

(Proof) Let  $G_1$  be a generator matrix of a linear  $[n_1, m, k+1]$ -code  $C_1$  with the dual minimum Hamming distance at least l+1. Let  $\Phi(Y)$  be an  $\epsilon$ -almost  $(n_2, m, k)$ -resilient function with the domain distance  $d_{\Phi} \geq l+1$ .

Consider a linear feedback shift register of length m and with a primitive feedback polynomial. Let S be the state transition matrix of such a shift register. Let  $X = (x_1, \dots, x_{n_1})$  and  $Y = (y_1, \dots, y_{n_2})$ . For  $i = 1, \dots, m$ , define

$$f_i(X,Y) \stackrel{\triangle}{=} \Phi(Y) \cdot S^{i-1}G_1X + g_i(Y)$$

where  $g_i(Y)$  is any Boolean function. Then we show that  $F(X,Y) = (f_1, \dots, f_m)$  satisfies  $(2^{m-1}\epsilon)$ -almost PC(l) of order k.

For  $(a_1, \dots, a_m) \neq (0, \dots, 0)$ , we have

$$a_1f_1 + \cdots + a_mf_m = \Phi(Y) \cdot (a_1I + a_2S + \cdots + a_mS^{m-1})G_1X + a_1g_1(Y) + \cdots + a_mg_m(Y).$$

It is easy to see that  $a_1I + a_2S + \cdots + a_mS^{m-1}$  is a permutation of the space  $\{0,1\}^m$ , as pointed out by Nyberg [12]. Therefore, this matrix is nonsingular. It implies that  $(a_1I + a_2D + \cdots + a_mD^{m-1})G_1$  is a generator matrix of the linear code  $C_1$ . Then from the proof of Theorem 4.1, we see that  $a_1f_1 + \cdots + a_mf_m$  satisfies  $(2^{m-1}\epsilon)$ -almost PC(l) of order k.

The rest of the proof is straitforward from Sec.5. Q.E.D.
