April 9, 2009

## Abstract

Various results show that oblivious transfer can be implemented using the assumption of *noisy channels*. Unfortunately, this assumption is not as weak as one might think, because in a cryptographic setting, these noisy channels must satisfy very strong security requirements.

*Unfair noisy channels*, introduced by Damgård, Kilian and Salvail [Eurocrypt '99], reduce these limitations: They give the adversary an unfair advantage over the honest player, and therefore weaken the security requirements on the noisy channel. However, this model still has many shortcomings: For example, the adversary's advantage is only allowed to have a very special form, and no error is allowed in the implementation.

In this paper we generalize the idea of unfair noisy channels. We introduce two new models of cryptographic noisy channels that we call the *weak erasure channel* and the *weak binary symmetric channel*, and show how they can be used to implement oblivious transfer. Our models are more general and use much weaker assumptions than unfair noisy channels, which makes implementation a more realistic prospect. For example, these are the first models that allows the parameters to come from experimental evidence.

## 1 Introduction

Secure two-party computation, introduced in [Yao82], allows two mutually distrustful players to calculate a function in a secure way. This means that both players get the correct output, but nothing more than that. Even though secure two-party computation is generally impossible without any further assumption, it has been shown in [GV88, Kil88] that if a very simple primitive called *oblivious transfer* is available, then any two-party computation can be implemented in an unconditionally secure way.

Oblivious transfer was first defined in [Wie83], however without realizing its connection to cryptography. In the cryptographic context, the two variants of oblivious transfer were defined in [Rab81] and [EGL85], which were shown to be equally powerful in [Cré88]. Throughout this work, we will only consider *chosen one-out-of-two oblivious transfer*, or OT for short. Here, a sender can send two message bits  $x_0$  and  $x_1$ , and a receiver can choose which of the two messages he wants to receive by sending a choice bit  $c$ . He receives  $x_c$ , but does not get to know the other message bit  $x_{1-c}$ , and the sender does not get to know the choice bit  $c$ . There exist various implementations of OT that are secure against computationally bounded adversaries, under various hardness assumptions. Against adversaries with unbounded computational power, OT can only be implemented if the players have access to an additional (weaker) functionality.

### 1.1 OT from (Unfair) Noisy Channels

In [CK88], it has been shown that OT can be implemented from various weaker forms of OT, as well as *noisy channels*. Therefore, noise is not always a bad thing; in a cryptographic context

it can become a valuable resource. These protocols have later been improved and generalized in [Cré97], [CMW04] and [NW08]. The basic idea of all these protocols is very similar: First, they construct some kind of erasure channel. Then, this erasure channel is used many times to implement OT. The correctness and the security is guaranteed using error correcting codes and privacy amplification.

These noisy channels seem to be quite weak primitives and easily implementable, but they have some rather strong requirements: The statistics of the channel must be *exactly* the same in every instance, and known to both players. And, apart from the output of the channel, a dishonest player must not get *any* additional output.

In [DKS99], weaker forms of noisy channels called *unfair noisy channels* were introduced. Unfair noisy channels are binary symmetric noisy channels that let the dishonest player change the error-rate in the channel by a certain amount. For example, this makes the protocol secure against an adversary that might use better transmitters or detectors in order to break the protocol. In this model, OT is implemented in a different way, using the following two steps. First, from only a few instances of the channel, a weak form of OT (called WOT) is constructed. In the second step, the security is amplified, i.e., many of these WOTs are used to get one secure instance of OT. The resulting protocol is only secure in the *semi-honest model*, i.e., under the assumption that the dishonest player follows the protocol. To make the protocol secure in the *malicious model*, where the dishonest player may deviate in an arbitrary way from the protocol, a third step is needed, which uses *bit commitments* and *zero-knowledge proofs* to force the dishonest player to follow the protocol.

The results from [DKS99] were later improved in [DFMS04], and OT amplification was improved in [Wul07].

## 1.2 Limitations of Unfair Noisy Channels

Even though unfair noisy channels are much weaker than (fair) noisy channels, they still have some very strong assumptions, which makes them hard to implement. Let us look at the following example:

A (fair) binary symmetric noisy channel with error  $\varepsilon$  lets a sender input a bit  $x \in \{0, 1\}$ . The channel then outputs a value  $Y \in \{0, 1\}$  to the receiver, where  $\Pr[Y \neq x] = \varepsilon$ . Let us assume that neither the sender nor the receiver can influence  $\varepsilon$ , but that the dishonest receiver gets an additional value  $E \in \{0, 1\}$ , where  $\Pr[E = 1] = \mu$ , and  $E = 1 \Rightarrow Y = x$ . Therefore, with some probability  $\mu$ , the dishonest receiver gets to know that the value  $Y$  he received is in fact equal to  $x$ . If  $\mu$  is small, then this channel is very close to a fair binary symmetric noisy channel. However, even then it cannot be modeled by an unfair noisy channel, because there, the receiver can only change the error probability of the channel in a certain range, but he can never be sure that his received bit is the bit sent by the sender. Therefore, unfair noisy channels forbid the adversary to have this kind of advantage.

Now, let us assume that we are given an implementation a noisy channel, and that the statistics of the channel show that the channel behaves like a fair noisy channel. The accuracy of these statistics are only *polynomial*. For example, the channel might as well be the channel from the example above, where  $\mu$  is polynomially small. Therefore, we cannot conclude that the channel is really a implementation of a fair noisy channel, and neither can the channel be modeled by an unfair noisy channel. To be able to implement OT in situations like this where the properties of the channel have to be determined by observation, we need to have a model that allows the implementation to behave *arbitrarily* with some probability.

### 1.3 Contribution

The goal of this work is to present new, more realistic models for noisy channels (called *weak noisy channels*) and to show that oblivious transfer can be implemented in an unconditionally secure way, assuming that such weak noisy channels exist. Opposed to the unfair noisy channel which is defined as an ideal functionality, our definitions are lists of conditions that a implementation of a weak noisy channels should satisfy. For a given implementation, one only needs to check these (quite simple) conditions, and does not need to show a cryptographically secure reduction of an ideal functionality to the implementation. This makes our model easier to apply.

We will introduce the following three models of weak noisy channels:

- *Weak erasure channels in the semi-honest model*<sup>1</sup> (*PassiveWEC*). These are weak variants of erasure channels<sup>2</sup> (channels that transmit a bit with some probability).
- *Weak binary symmetric channels in the semi-honest model* (*PassiveWBSC*). As the unfair noisy channel, these are weak variants of binary symmetric channels.
- *Weak erasure channels in the malicious model* (*ActiveWEC*).

We defined these channels such that they fitted well into the protocol proposed in [DKS99], which is the only protocol we know of to implement OT from weak noisy channels.

To illustrate the flexibility and generality of our models, we show that it is very easy to implement a *PassiveWEC* from *Gaussian channels*, and that the (passive) unfair noisy channel can be seen as an instance of a *PassiveWBSC*.

In Sections 3 and 4, we show that *PassiveWEC* implies WOT, and *PassiveWBSC* implies *PassiveWEC* in the semi-honest model. Then, in Section 5, we show that *ActiveWEC* implies both bit commitment and a committed version of *PassiveWEC* in the malicious model. This implies that in a certain range of parameters, each of the three weak noisy channels allows for any secure two-party computation to be achieved. For each of the weak noisy channels, we also present a *simulation* of the channel using nothing else than noiseless communication, and in the case of *ActiveWEC*, shared randomness. Since it is impossible to implement bit commitment or oblivious transfer from noiseless communication and shared randomness, it is also impossible to implement them using the simulated weak noisy channels.

## 2 Preliminaries

We start with some basic definitions and lemmas that we will need later.

We will use the following convention: Lower case letters will denote fixed values and upper case letters will denote random variables. Calligraphic letters will denote sets and domains of random variables. For a random variable  $X$  over  $\mathcal{X}$ , we denote its distribution by  $P_X : \mathcal{X} \rightarrow [0, 1]$  with  $\sum_{x \in \mathcal{X}} P_X(x) = 1$ . For a given distribution  $P_{XY} : \mathcal{X} \times \mathcal{Y} \rightarrow [0, 1]$ , we write for the marginal distribution  $P_X(x) := \sum_{y \in \mathcal{Y}} P_{XY}(x, y)$  and, if  $P_Y(y) \neq 0$ ,  $P_{X|Y}(x | y) := P_{XY}(x, y)/P_Y(y)$  for the conditional distribution. Let  $h(x) := -x \log x - (1 - x) \log(1 - x)$  be the binary entropy function.

---

<sup>1</sup>See Section 2.2 for explanation of the semi-honest and the malicious model.

<sup>2</sup>Note that the original definition of OT by Rabin [Rab81] is in fact also an erasure channel, so a WEC is also a weak form of Rabin OT.

## 2.1 Statistical Distance and Maximal Bit-Prediction Advantage

The *statistical distance* of two distributions  $P_X$  and  $P_Y$  over the same domain  $\mathcal{U}$  is defined as

$$\delta(P_X, P_Y) := \frac{1}{2} \sum_{u \in \mathcal{U}} |P_X(u) - P_Y(u)|.$$

It is easy to show that

$$\delta(P_X, P_Y) = \max_f |\Pr[f(X) = 1] - \Pr[f(Y) = 1]|. \quad (2.1)$$

For a distribution  $P_{XY}$  over  $\{0, 1\} \times \mathcal{Y}$ , the *maximal bit-prediction advantage* of  $X$  from  $Y$  is defined as

$$\text{PredAdv}(X | Y) := 2 \cdot \max_f \Pr[f(Y) = X] - 1.$$

Lemmas 1, 2 and 3 give some intuition about these measures: The random variable  $B$  (or  $C$ ) indicates that an error occurred: If  $B = 0$ , everything is fine. But if  $B = 1$ , the adversary may have complete knowledge. For proofs of Lemmas 1 and 2, see for example [Wul07] and [Hol06].

**Lemma 1.** *Let  $P_{BX}$  and  $P_{CY}$  be distributions over  $\{0, 1\} \times \mathcal{U}$  such that  $\Pr[B = 1] = \Pr[C = 1] = \varepsilon$ . Then  $\delta(P_X, P_Y) \leq \varepsilon + (1 - \varepsilon) \cdot \delta(P_{X|B=0}, P_{Y|C=0})$ .*

**Lemma 2.** *Let  $P_{XY}$  be a distribution over  $\{0, 1\} \times \mathcal{Y}$ . There exists a conditional distribution  $P_{B|XY}$  over  $\{0, 1\} \times \{0, 1\} \times \mathcal{Y}$  such that  $\Pr[B = 1] \leq \text{PredAdv}(X | Y)$  and  $\text{PredAdv}(X | Y, B = 0) = 0$ .*

**Lemma 3.** *Let  $P_{XY}$  be a distribution over  $\{0, 1\} \times \mathcal{Y}$  with  $\delta(P_{Y|X=0}, P_{Y|X=1}) \leq \varepsilon$ . There exists a random variable  $B$  over  $\{0, 1\}$  such that  $\Pr[B = 1 | X = 0] = \Pr[B = 1 | X = 1] = \varepsilon$ , and  $P_{Y|X=0, B=0} = P_{Y|X=1, B=0}$ .*

*Proof.* We define  $B$  as

$$P_{B|XY}(0 | x, y) := \frac{\min(P_{Y|X}(y | 0), P_{Y|X}(y | 1))}{P_{Y|X}(y | x)}.$$

For  $x \in \{0, 1\}$ , we get

$$\begin{aligned} \Pr[B = 1 | X = x] &= \sum_y P_{Y|X}(y | x) P_{B|XY}(1 | x, y) \\ &= \sum_y P_{Y|X}(y | x) \left( 1 - \frac{\min(P_{Y|X}(y | 0), P_{Y|X}(y | 1))}{P_{Y|X}(y | x)} \right) \\ &= \sum_y (P_{Y|X}(y | x) - \min(P_{Y|X}(y | 0), P_{Y|X}(y | 1))) \\ &= \delta(P_{Y|X=0}, P_{Y|X=1}). \end{aligned}$$

For all  $y$ , we have

$$\begin{aligned} \Pr[Y = y | X = 0, B = 0] &= \frac{\Pr[Y = y | X = 0] \cdot \Pr[B = 0 | X = 0, Y = y]}{\Pr[B = 0 | X = 0]} \\ &= \frac{\min(P_{Y|X}(y | 0), P_{Y|X}(y | 1))}{\Pr[B = 0 | X = 0]} \\ &= \frac{\min(P_{Y|X}(y | 0), P_{Y|X}(y | 1))}{\Pr[B = 0 | X = 1]} \\ &= \Pr[Y = y | X = 1, B = 0] \end{aligned}$$

Finally, if  $\delta(P_{Y|X=0}, P_{Y|X=1}) < \varepsilon$ , we can additionally increase  $\Pr[B = 1 | X = x]$ , without violating the condition.  $\square$

**Lemma 4.** *Let  $P_{BXY}$  be any distribution over  $\{0, 1\} \times \{0, 1\} \times \mathcal{Y}$ . We have*

$$\begin{aligned} \text{PredAdv}(X | Y) &\leq \Pr[B = 0] \cdot \text{PredAdv}(X | Y, B = 0) \\ &\quad + \Pr[B = 1] \cdot \text{PredAdv}(X | Y, B = 1). \end{aligned}$$

*Proof.* Let  $f$  be a function that maximizes  $\text{PredAdv}(X | Y)$ . We have

$$\begin{aligned} \text{PredAdv}(X | Y) &= \Pr[B = 0] \cdot (2 \cdot \Pr[f(Y) = X | B = 0] - 1) \\ &\quad + \Pr[B = 1] \cdot (2 \cdot \Pr[f(Y) = X | B = 1] - 1) \\ &\leq \Pr[B = 0] \cdot \text{PredAdv}(X | Y, B = 0) \\ &\quad + \Pr[B = 1] \cdot \text{PredAdv}(X | Y, B = 1). \end{aligned}$$

$\square$

**Lemma 5.** *Let  $(X, Y)$  be distributed according to  $P_{XY}$  over  $\{0, 1\} \times \mathcal{Y}$  with  $\text{PredAdv}(X) \leq a$  and  $\delta(P_{Y|X=0}, P_{Y|X=1}) \leq b$ . Then  $\text{PredAdv}(X | Y) \leq 1 - (1 - a)(1 - b)$ .*

*Proof.* We can apply Lemma 3, which defines a random variable  $B$  such that

$$\Pr[B = 1 | X = 0] = \Pr[B = 1 | X = 1] = b$$

and  $P_{Y|B=0, X=0} = P_{Y|B=0, X=1}$ . We have

$$\Pr[X = x | B = 0] = \frac{\Pr[X = x] \cdot (1 - b)}{\Pr[X = 0] \cdot (1 - b) + \Pr[X = 1] \cdot (1 - b)} = \Pr[X = x].$$

From Lemma 4 follows that

$$\begin{aligned} \text{PredAdv}(X | Y) &\leq (1 - b) \cdot \text{PredAdv}(X | Y, B = 0) + b \cdot \text{PredAdv}(X | Y, B = 1) \\ &\leq (1 - b) \cdot \text{PredAdv}(X | B = 0) + b \\ &\leq (1 - b) \cdot a + b \\ &= 1 - (1 - a)(1 - b). \end{aligned}$$

Note that  $\text{PredAdv}(X | B = 0) = \text{PredAdv}(X)$ .  $\square$

The following Lemma is a simplified, information-theoretic version of the *degradation lemma* from [HR08].

**Lemma 6.** *Let  $P_{X_0V_0}$  and  $P_{X_1V_1}$  be two distributions over  $\{0, 1\} \otimes \mathcal{V}$ , and let  $c \in \{0, 1\}$  be a constant. If we have*

$$\delta(P_{V_i|X_i=0}, P_{V_i|X_i=1}) \leq \varepsilon_i,$$

for  $i \in \{0, 1\}$ , then

$$\delta(P_{V_0V_1|X_0=0, X_0 \oplus X_1=c}, P_{V_0V_1|X_0=1, X_0 \oplus X_1=c}) \leq 1 - (1 - \varepsilon_0)(1 - \varepsilon_1).$$

*Proof.* We apply Lemma 3, which gives us two independent random variables  $B_0$  and  $B_1$ , such that for  $i \in \{0, 1\}$  and  $x_i \in \{0, 1\}$ ,

$$P_{V_i|X_i=0, B_i=0} = P_{V_i|X_i=1, B_i=0}$$

and

$$\Pr[B_i = 1 \mid X_i = 0] = \Pr[B_i = 1 \mid X_i = 1] = \varepsilon_i .$$

Let  $B = \max(B_0, B_1)$ . We get

$$\Pr[B = 1 \mid X_0 = 0, X_0 \oplus X_1 = c] = \Pr[B = 1 \mid X_0 = 1, X_0 \oplus X_1 = c] = 1 - (1 - \varepsilon_0)(1 - \varepsilon_1)$$

and

$$P_{V_0 V_1|X_0=0, X_0 \oplus X_1=c, B=0} = P_{V_0 V_1|X_0=1, X_0 \oplus X_1=c, B=0} .$$

The statement follows from Lemma 1. □

## 2.2 Adversaries

We distinguish between two different models, the *semi-honest model* and the *malicious model*. In the *semi-honest model*, the adversary is *passive*, which means that he follows the protocol, but may try to get additional knowledge from the messages received. In the malicious model, the adversary is *active*, which means that he may change his behavior in an arbitrary way.

## 2.3 Randomized Functionalities

All our channels are randomized, because the security conditions tend to be more intuitive this way. But randomized channels are usually also easier to implement (See for example Protocol ActiveToPassiveWEC in Section 5.3). The results for randomized channels immediately imply similar conditions for non-randomized channel, as a non-randomized channel can be converted into a randomized channel simply by requiring the players to choose their inputs at random. Our definitions are weak enough that this works even in the malicious case.

## 2.4 Oblivious Transfer Amplification

Our work is based on *oblivious transfer amplification* from [DKS99, Wul07], which gives a way to implement oblivious transfer (OT) from weak oblivious transfer (WOT). We will take the definition of WOT from the full version of [Wul07], however we use the weaker requirement of  $\text{PredAdv}(C \mid U) \leq p$  instead of  $\text{PredAdv}(C \mid U, E) \leq p$ . As explained there, the reduction of OT to WOT still works for this weaker definition, as long as the error correction is always done from the sender to the receiver, which is normally the case.

**Definition 1** (WOT, semi-honest model). A *weak (randomized) oblivious transfer*, denoted by  $(p, q, \varepsilon)$ -WOT, is a primitive between a sender and a receiver, that outputs  $(X_0, X_1)$  to the honest sender and  $(C, Y)$  to the honest receiver. Let  $U$  be the additional auxiliary output<sup>3</sup> to a dishonest sender and let  $V$  be the auxiliary output to a dishonest receiver. Let  $E := X_C \oplus Y$ . The following conditions must be satisfied:

- Correctness:  $\Pr[E = 1] \leq \varepsilon$ .
- Receiver Security:  $\text{PredAdv}(C \mid U) \leq p$ .

---

<sup>3</sup>Or the *view* of the adversary, i.e., everything he knows at the end of the protocol.

- Sender Security:  $\text{PredAdv}(X_{1-C} | V, E) \leq q$ .

**Theorem 1** ([Wul07]). *Let  $p, q$  and  $\varepsilon$  be constants such at least one of the following conditions holds:*

$$p + q + 2\varepsilon \leq 0.24, \quad 22q + 44\varepsilon < 1 - p, \quad 22p + 44\varepsilon < 1 - q, \quad 49p + 49q < (1 - 2\varepsilon)^2,$$

$$q = 0 \wedge p < (1 - 2\varepsilon)^2, \quad p = 0 \wedge q < (1 - 2\varepsilon)^2, \quad \varepsilon = 0 \wedge p + q < 1.$$

*Then there exists a protocol that efficiently implements OT from  $(p, q, \varepsilon)$ -WOT secure in the semi-honest model.*

We will only use the first four bounds, because we assume that  $p, q, \varepsilon > 0$ .

## 2.5 Bit Commitment

To achieve oblivious transfer in the malicious model, we will need *bit commitments*. A bit commitment scheme is a pair of protocols, a **Commit** protocol and a **Open** protocol, executed between a committer and a receiver. The players first execute the Commit protocol, where the committer has an input  $b$ . Then, they may also execute the Open protocol. After the Open protocol, the receiver either accepts or rejects. If he accepts, he gets a value  $b'$ . The protocols are  $\varepsilon$ -secure, if they satisfy the following properties:

- *Correctness*: If both players follow the protocols, then the receiver rejects with a probability smaller than  $\varepsilon$ , and if he accepts, he outputs  $b' = b$  with probability at least  $1 - \varepsilon$ .
- *Binding*: If the receiver is honest, then for any malicious sender, with probability  $1 - \varepsilon$ , there exists at most one value after the commit protocol that the receiver will accept with a probability bigger than  $\varepsilon$  in the open phase.
- *Hiding*: If the committer is honest, then no malicious receiver gets to know  $b$  with a probability bigger than  $\varepsilon$ .<sup>4</sup>

## 3 Weak Erasure Channel in the Semi-Honest Model

In this section, we present a reduction of WOT to *weak erasure channels (WEC)* in the semi-honest model. A weak erasure channel lets a honest sender send a bit, which is then received by the honest receiver with a certain probability, and gets lost otherwise. Dishonest players are allowed to receive some additional information, so a dishonest receiver may get to know some information about the input even in the case where the channel lost the bit, and a dishonest sender may get information about whether the bit has been lost or not.

**Definition 2** (WEC, semi-honest model).  $(d_0, d_1, p, q, \varepsilon)$ -PassiveWEC is a primitive where the honest sender has output  $X \in \{0, 1\}$  and the honest receiver has output  $Y \in \{0, 1, \Delta\}$ . Furthermore, the dishonest sender may receive an additional value  $U$ , and the dishonest receiver may receive an additional value  $V$ . These values must satisfy the following conditions:

- *Correctness*:  $\Pr[Y = \Delta] \in [d_0, d_1]$ ,  $\Pr[Y \neq X | Y \neq \Delta] \leq \varepsilon$ .
- *Receiver Security*:  $\delta(P_{XU|Y \neq \Delta}, P_{XU|Y = \Delta}) \leq p$ .

---

<sup>4</sup>This means that if  $b \in \{0, 1\}$  and  $V$  is the receiver's view, then we require that  $\delta(P_{V|B=0}, P_{V|B=1}) \leq \varepsilon$ .

- *Sender Security*:  $\text{PredAdv}(X | V, Y = \Delta) \leq q$ .

The parameters can be interpreted as follows:  $d_0, d_1$  and  $\varepsilon$  are parameters of the honest players. The probability that the output of the channel is  $\Delta$  is in the interval  $[d_0, d_1]$ . (Defining this as an interval gives some freedom to the implementation, which may be important, as parameters are almost never known precisely.)  $\varepsilon$  is the probability that the output of the honest receiver is wrong, if the output is not  $\Delta$ . According to Lemma 2,  $q$  is the probability that the dishonest receiver gets to know the input of the channel, given that the output of the channel is  $\Delta$ , and according to Lemma 3,  $p$  is the probability that a dishonest sender gets to know whether  $Y = \Delta$  or  $Y \neq \Delta$ .

### 3.1 Simulation of PassiveWEC

We start by showing for which values a PassiveWEC can be simulated by only using noiseless communication. Since OT cannot be implemented from noiseless communication, such a PassiveWEC therefore cannot be used to implement OT. Note that in any simulation that only uses noiseless communication, we always have  $d_0 = d_1$ , as both players know all the probabilities. In the following simulation, we require that  $\varepsilon \in [0, \frac{1}{2}]$ ,  $d, g \in [0, 1]$ , and  $g \geq (1 - 2\varepsilon)(1 - d)$ .

Protocol  $\text{SimWEC}(d, \varepsilon, g)$

1. The sender chooses  $x$  uniformly at random and sends the receiver  $m := x$  with probability  $g$ , and  $m := \Delta$  otherwise. The sender outputs  $x$ .
2. If the receiver gets  $m \in \{0, 1\}$ , he outputs  $y := m$  with probability  $\frac{(1-2\varepsilon)(1-d)}{g}$ , and  $y := \Delta$  otherwise.
3. If the receiver gets  $m = \Delta$ , he outputs  $y$  chosen at random with probability  $\frac{2\varepsilon(1-d)}{1-g}$ , and  $y := \Delta$  otherwise.

**Theorem 2.** *For any  $d, \varepsilon, p$  and  $q$ , where  $p+q+2\varepsilon \geq 1$ ,  $(d, d, p, q, \varepsilon)$ -PassiveWEC is simulatable in the semi-honest model.*

*Proof.* We choose  $g := (1 - 2\varepsilon)(1 - d) + qd$  and use Protocol  $\text{SimWEC}(d, \varepsilon, g)$ . We get

$$\Pr[Y = \Delta] = g \left( 1 - \frac{(1 - 2\varepsilon)(1 - d)}{g} \right) + (1 - g) \left( 1 - \frac{2\varepsilon(1 - d)}{1 - g} \right) = d$$

and

$$\Pr[X \neq Y | Y \neq \Delta] = \frac{\frac{1}{2} \cdot 2\varepsilon(1 - d)}{2\varepsilon(1 - d) + (1 - 2\varepsilon)(1 - d)} = \varepsilon.$$

Therefore

$$\Pr[M = X | Y = \Delta] = \frac{\Pr[M = X, Y = \Delta]}{\Pr[Y = \Delta]} = \frac{g - (1 - 2\varepsilon)(1 - d)}{d} \quad (3.1)$$

and hence

$$\begin{aligned} \text{PredAdv}(X | M, Y = \Delta) &= \Pr[M = X | Y = \Delta] \\ &= \frac{g - (1 - 2\varepsilon)(1 - d)}{d} = q. \end{aligned}$$

Furthermore, we have

$$\Pr[M = X \mid Y \neq \Delta] = \frac{\Pr[M = X, Y \neq \Delta]}{\Pr[Y \neq \Delta]} = \frac{(1 - 2\varepsilon)(1 - d)}{1 - d} = 1 - 2\varepsilon.$$

Using Eq. 3.1, we get

$$\begin{aligned} \delta(P_{XU|Y \neq \Delta}, P_{XU|Y = \Delta}) &= \left| \Pr[M = X \mid Y \neq \Delta] - \Pr[M = X \mid Y = \Delta] \right| \\ &= \left| 1 - 2\varepsilon - \frac{g - (1 - 2\varepsilon)(1 - d)}{d} \right| \\ &= \frac{1 - g - 2\varepsilon}{d} = 1 - 2\varepsilon - q \leq p. \end{aligned}$$

□

### 3.2 WOT from PassiveWEC

Protocol PassiveWECtoWOT

1. The sender and the receiver execute PassiveWEC twice. The sender receives  $(x_0, x_1)$ , the receiver  $(y_0, y_1)$ .
2. If there exists a  $c$ , such that  $y_c \neq \Delta$  and  $y_{1-c} = \Delta$ , then the receiver sets  $y := y_c$ , outputs  $(c, y)$ , tells the sender to terminate the protocol and terminates.
3. If the sender receives the message to terminate the protocol, he outputs  $(x_0, x_1)$  and terminates. Otherwise, they restart the protocol.

**Theorem 3.** *Protocol PassiveWECtoWOT securely implements a*

$$\left( 1 - \frac{2d_0(1 - d_1)}{d_1(1 - d_0) + d_0(1 - d_1)}(1 - p)^2, q, \varepsilon \right)\text{-WOT}$$

*secure against passive adversaries out of  $(d_0, d_1, p, q, \varepsilon)$ -PassiveWEC. The expected number of instances used is at most  $1/\min(2d_0(1 - d_0), 2d_1(1 - d_1))$ .*

*Proof.* In the following, let  $X = (X_0, X_1)$  be the output of the honest sender,  $C$  and  $Y$  be the outputs of the honest receiver, and  $E = Y \oplus X_C$ .

From Lemma 26 follows that in every iteration, the probability of the protocol to terminate is at least  $\min(2d_0(1 - d_0), 2d_1(1 - d_1))$ , from which follows that the expected number of instances used by this protocol is at most  $1/\min(2d_0(1 - d_0), 2d_1(1 - d_1))$ . If the protocol terminates, the output is equal to the value that is not  $\Delta$ . By the definition of PassiveWEC, the output is correct with a probability of at least  $1 - \varepsilon$ .

Let  $V$  be the additional output of the dishonest receiver. We have  $V = (C, Y, Y_0, Y_1, V_0, V_1)$ , where  $Y_0$  and  $Y_1$  are the the outputs of the honest, and  $V_0$  and  $V_1$  the additional outputs of the dishonest receiver of the two instances of PassiveWEC in the last round. All the outputs of the other rounds are independent and can be omitted. Since two instances of PassiveWEC in the last round are independent of each other, we get

$$\begin{aligned} \text{PredAdv}(X_{1-C} \mid V, E) &= \text{PredAdv}(X_{1-C} \mid C, Y, Y_0, Y_1, V_0, V_1, E, Y_C \neq \Delta, Y_{1-C} = \Delta) \\ &= \text{PredAdv}(X_{1-C} \mid V_{1-C}, Y_{1-C} = \Delta) \leq q. \end{aligned}$$

Let  $U$  be the additional output of the dishonest sender. We have  $U = (X_0, X_1, U_0, U_1)$ , where  $U_0$  and  $U_1$  are the additional outputs of the dishonest sender of the two instances of **PassiveWEC** in the last round. Again, all the outputs of the other rounds are independent and can be omitted. We can apply Lemma 6 and get

$$\delta(P_{X_0 U_0 X_1 U_1 | C=0, \mathcal{A}}, P_{X_0 U_0 X_1 U_1 | C=1, \mathcal{A}}) \leq 1 - (1 - p)^2,$$

where  $\mathcal{A}$  is the event that there exists a  $c$ , such that  $y_c \neq \Delta$  and  $y_{1-c} = \Delta$ . From Lemma 25 follows that  $C$  is maximally biased if  $\Pr[Y_0 = \Delta] = d_0$  and  $\Pr[Y_1 = \Delta] = d_1$  (or vice versa). It follows that

$$\text{PredAdv}(C) \leq 2 \frac{d_1(1 - d_0)}{d_1(1 - d_0) + d_0(1 - d_1)} - 1 = 1 - 2 \frac{d_0(1 - d_1)}{d_1(1 - d_0) + d_0(1 - d_1)}.$$

Finally, it follows from Lemma 5 that

$$\text{PredAdv}(C | U) = \text{PredAdv}(C | U_0, U_1, X) \leq 1 - 2 \frac{d_0(1 - d_1)}{d_1(1 - d_0) + d_0(1 - d_1)} (1 - p)^2.$$

□

Note that for the stronger requirement of  $\text{PredAdv}(C | U, E)$  from the definition of WOT in [Wul07], we would not be able to achieve the same bound: If, for example, the first **PassiveWEC** always has an error with probability  $\varepsilon$ , but the second has no error, then knowing that an error occurred would tell the sender that  $C = 0$ .

Corollary 1 follows now from Theorem 1, Theorem 3 and

$$1 - 2d_0(1 - d_1)w(1 - p)^2 \leq 2p + (d_1 - d_0)w.$$

**Corollary 1.** *Let  $d_0 \leq d_1$ ,  $p$ ,  $q$  and  $\varepsilon$  be constants, and let  $w = 1/(d_1(1 - d_0) + d_0(1 - d_1))$ . If at least one of the conditions*

$$2p + q + (d_1 - d_0)w + 2\varepsilon \leq 0.24, \quad 11q + 22\varepsilon < d_0(1 - d_1)w(1 - p)^2,$$

$$44p + 22(d_1 - d_0)w + 44\varepsilon < 1 - q, \quad 98p + 49q + 49(d_1 - d_0)w < (1 - 2\varepsilon)^2$$

*holds, then there exists a protocol that uses  $(d_0, d_1, p, q, \varepsilon)$ -PassiveWEC and efficiently implements OT secure in the semi-honest model.*

### 3.3 An Example: The Gaussian Channel

The *Gaussian channel* is often used in information theory as a model of a noisy channel, because it models real physical channels quite well. It has been shown that a perfect and fair Gaussian channel implies bit commitment, see [NSBI07, OM08]. A Gaussian channel is a channel where the sender has input  $x_g \in \mathbb{R}$  and the receiver has output  $Y_g = x_g + E_g$ , where  $E_g \sim \mathcal{N}(0, 1)$ , i.e., the channel has an additive error that is normal distributed.

We can easily implement a **PassiveWEC** from this channel in the following way: Let  $a, b \in \mathbb{R}^+$ . The sender chooses  $x \in \{0, 1\}$  uniformly at random, sends  $x_g := (2x - 1)a$  and outputs  $x$ . The receiver gets  $y_g$ , and outputs  $y = \Delta$  if  $|y_g| \leq b$ ,  $y = 1$  if  $y_g > b$  and  $y = 0$  otherwise. With an arbitrary small error, we can make the Gaussian channel discrete. In the limit, we get a  $(d, d, p, q, \varepsilon)$ -PassiveWEC, where  $d = \Phi(b - a) - \Phi(-a - b)$ ,  $\varepsilon = \frac{\Phi(-a - b)}{1 - d}$ ,  $p = 0$  and  $q = 2 \frac{\Phi(b - a) - \Phi(-a)}{d} - 1$ . Choosing for example  $a = 1$  and  $b = 2.5$ , we get  $d \approx 0.93296$ ,  $\varepsilon \leq 0.0035$ , and  $q \leq 0.6604$ . Since  $44 \cdot \varepsilon < 1 - q$ , it follows from Corollary 1 that oblivious transfer can be

implemented. Together with the bit commitment protocols from [NSBI07, OM08], this implies (using a protocol similar to `ActiveToPassiveWEC`) that OT can be implemented from (perfect and fair) Gaussian channels in the malicious model.

To the best of our knowledge, this has not been known before, as previous results in [CMW04, NW08] rely on the fact that the channel is discrete and cannot be applied to the Gaussian channel. Note that in contrast to the reductions from [NSBI07, OM08], our reduction even works for Gaussian channels that are neither perfect nor fair.

## 4 Weak Binary Symmetric Channel in the Semi-Honest Model

Weak Binary Symmetric Channel is a weak form of a binary symmetric channel. The channel transmits the input bit of the sender to the receiver, but flips the bit with some probability. Again, the definition is randomized.

**Definition 3** (WBSC, semi-honest model).  $(\varepsilon, \varepsilon_0, \varepsilon_1, p, q)$ -PassiveWBSC is defined as follows: The honest sender has output  $X \in \{0, 1\}$  and the honest receiver has output  $Y \in \{0, 1\}$ . Furthermore, the dishonest sender may receive an additional value  $U$ , and the dishonest receiver may receive an additional value  $V$ . These values must satisfy the following conditions:

- *Correctness*:  $\Pr[X = 0] \in [\frac{1-\varepsilon}{2}, \frac{1+\varepsilon}{2}]$ , and for  $x \in \{0, 1\}$ ,  $\Pr[Y \neq X \mid X = x] \in [\varepsilon_0, \varepsilon_1]$ .
- *Receiver Security*:  $\delta(P_{UX|Y=X}, P_{UX|Y \neq X}) \leq p$ .
- *Sender Security*: For all  $y \in \{0, 1\}$ :  $\delta(P_{V|X=0, Y=y}, P_{V|X=1, Y=y}) \leq q$ .

The parameters can be interpreted as follows:  $\varepsilon$  is the maximal bias of  $X$ , and  $\varepsilon_0$  and  $\varepsilon_1$  define the error interval of the honest players. From Lemma 3 it follows that  $p$  is the probability that the sender, and  $q$  is the probability that the receiver gets to know whether  $X = Y$  or not. Note that in order to make our reduction work, the sender security has a slightly different form than the receiver security. If  $\varepsilon = 0$  and  $\varepsilon_0 = \varepsilon_1$ , the sender security implies  $\delta(P_{VY|Y=X}, P_{VY|Y \neq X}) \leq q$ . So in this case, the sender security is strictly stronger than the receiver security.

### 4.1 Simulation of PassiveWBSC

The following simulation is basically the same as in [DKS99] for the unfair noisy channel. Let  $\varepsilon_A, \varepsilon_B \in [0, \frac{1}{2}]$ .

Protocol  $\text{SimWBSC}(\varepsilon_A, \varepsilon_B)$

1. The players toss a uniform coin  $M \in \{0, 1\}$ .
2. The sender calculates  $X := 1 - M$  with probability  $\varepsilon_A$  and  $X := M$  otherwise, and outputs  $X$ .
3. The receiver calculates  $Y := 1 - M$  with probability  $\varepsilon_B$  and  $Y := M$  otherwise, and outputs  $Y$ .

**Theorem 4.** Protocol  $\text{SimWBSC}(\varepsilon_A, \varepsilon_B)$  securely implements a  $(0, \varepsilon, \varepsilon, p, q)$ -PassiveWBSC in the semi-honest model, where  $\varepsilon := \varepsilon_A(1 - \varepsilon_B) + \varepsilon_B(1 - \varepsilon_A)$ ,  $p := \frac{(1-\varepsilon_A)(1-\varepsilon_B)}{1-\varepsilon} - \frac{\varepsilon_A(1-\varepsilon_B)}{\varepsilon}$  and  $q := \frac{(1-\varepsilon_A)(1-\varepsilon_B)}{1-\varepsilon} - \frac{(1-\varepsilon_A)\varepsilon_B}{\varepsilon}$ .

*Proof.* We have  $\Pr[Y \neq X] = \varepsilon_A(1 - \varepsilon_B) + (1 - \varepsilon_A)\varepsilon_B = \varepsilon$  and  $\Pr[Y = X] = 1 - \varepsilon$ . Since  $U = M$  and  $V = M$ , it follows that

$$\begin{aligned} \delta(P_{UX|Y=X}, P_{UX|Y \neq X}) &= 2 \Pr[M = X = 0 \mid Y = X] - 2 \Pr[M = X = 0 \mid Y \neq X] \\ &= \frac{(1 - \varepsilon_A)(1 - \varepsilon_B)}{1 - \varepsilon} - \frac{\varepsilon_A(1 - \varepsilon_B)}{\varepsilon}, \end{aligned}$$

and for all  $y \in \{0, 1\}$

$$\begin{aligned} \delta(P_{V|X=0, Y=y}, P_{V|X=1, Y=y}) &= \Pr[M = 0 \mid X = 0, Y = y] - \Pr[M = 0 \mid X = 1, Y = y] \\ &= \frac{(1 - \varepsilon_A)(1 - \varepsilon_B)}{1 - \varepsilon} - \frac{(1 - \varepsilon_A)\varepsilon_B}{\varepsilon}. \end{aligned}$$

□

Theorem 4 implies that  $(0, \varepsilon, \varepsilon, p, q)$ -PassiveWBSC is simulatable if  $p + q > 1$ .

## 4.2 PassiveWEC from PassiveWBSC

We will now give a reduction of PassiveWEC to PassiveWBSC. The protocol itself has already been used in [CK88], [Cr 97] and [DKS99]. The intuition behind the following protocol is simple: The sender sends a bit twice over a binary noisy channel. If the receiver gets twice the same message, he knows (with a small error) what the sender has sent and outputs that. If he receives two different messages, he does not know the input and outputs  $\Delta$ . Note that since two channels are randomized, the sender cannot choose his input, and therefore has to additionally send  $x_0 \oplus x_1$ .

Protocol PassiveWBSCtoWEC

1. The players execute PassiveWBSC twice. The sender gets  $(x_0, x_1)$ , the receiver  $(y_0, y_1)$ .
2. The sender sends  $m := x_0 \oplus x_1$  to the receiver and outputs  $x := x_0$ .
3. If  $y_0 \oplus y_1 = m$ , the receiver outputs  $y := y_0$ . Otherwise, he outputs  $y := \Delta$ .

**Theorem 5.** *Let*

$$\begin{aligned} d_0 &:= \min(2\varepsilon_0(1 - \varepsilon_0), 2\varepsilon_1(1 - \varepsilon_1)), \\ d_1 &:= \max(2\varepsilon_0(1 - \varepsilon_0), 2\varepsilon_1(1 - \varepsilon_1), \varepsilon_0(1 - \varepsilon_1) + \varepsilon_1(1 - \varepsilon_0)), \\ \varepsilon' &:= \frac{\varepsilon_1 - \varepsilon_0}{\varepsilon_0(1 - \varepsilon_1) + \varepsilon_1(1 - \varepsilon_0)} + \frac{2\varepsilon}{1 + \varepsilon^2}. \end{aligned}$$

Protocol PassiveWBSCtoWEC securely implements a

$$\left( d_0, d_1, 1 - (1 - p)^2, 1 - (1 - \varepsilon')(1 - q)^2, \frac{\varepsilon_1^2}{\varepsilon_1^2 + (1 - \varepsilon_1)^2} \right)\text{-PassiveWEC}$$

in the semi-honest model out of two instances of  $(\varepsilon, \varepsilon_0, \varepsilon_1, p, q)$ -PassiveWBSC.

*Proof.* It follows from Lemma 24 that

$$\Pr[Y \neq X \mid Y \neq \Delta] \leq \frac{\varepsilon_1^2}{\varepsilon_1^2 + (1 - \varepsilon_1)^2},$$

and from Lemma 26 that

$$\Pr[Y = \Delta] \in [d_0, d_1].$$

Let  $V_0$  and  $V_1$  be the additional information a dishonest receiver gets in the two executions of the PassiveWBSC. We have  $V := (M, V_0, V_1, Y_0, Y_1)$ . Using Lemma 6, we get

$$\delta(P_{V_0 V_1 | X=0, M=m, Y_0=y_0, Y_1=y_1}, P_{V_0 V_1 | X=1, M=m, Y_0=y_0, Y_1=y_1}) \leq 1 - (1 - q)^2.$$

We can bound

$$\begin{aligned} & \Pr[X = x \mid Y_0 = y_0, Y_1 = y_1, M = m, Y = \Delta] \\ &= \frac{\Pr[X = x, Y_0 = y_0, Y_1 = y_1, M = m, Y = \Delta]}{\Pr[Y_0 = y_0, Y_1 = y_1, K = m, Y = \Delta]} \\ &\leq \frac{\max_{|c|, |c'| \leq \varepsilon} \max_{a, b, c, d \in [\varepsilon_0, \varepsilon_1]} \frac{\frac{1+c}{2} a \cdot \frac{1+c'}{2} (1-b)}{\frac{1+c}{2} a \cdot \frac{1+c'}{2} (1-b) + \frac{1-c}{2} c \cdot \frac{1-c'}{2} (1-d)}}{\frac{\frac{1+\varepsilon}{2} \varepsilon_1 \cdot \frac{1+\varepsilon}{2} (1-\varepsilon_0)}{\frac{1+\varepsilon}{2} \varepsilon_1 \cdot \frac{1+\varepsilon}{2} (1-\varepsilon_0) + \frac{1-\varepsilon}{2} \varepsilon_0 \cdot \frac{1-\varepsilon}{2} (1-\varepsilon_1)}} \\ &\leq \frac{(1+\varepsilon)\varepsilon_1 \cdot (1+\varepsilon)(1-\varepsilon_0)}{(1+\varepsilon)\varepsilon_1 \cdot (1+\varepsilon)(1-\varepsilon_0) + (1-\varepsilon)\varepsilon_0 \cdot (1-\varepsilon)(1-\varepsilon_1)}, \end{aligned}$$

from which follows

$$\begin{aligned} & \text{PredAdv}(X \mid Y_0 = y_0, Y_1 = y_1, M = m, Y = \Delta) \\ &= 2 \max_x \Pr[X = x \mid Y_0 = y_0, Y_1 = y_1, M = m, Y = \Delta] - 1 \\ &\leq \frac{(1+\varepsilon)\varepsilon_1 \cdot (1+\varepsilon)(1-\varepsilon_0) - (1-\varepsilon)\varepsilon_0 \cdot (1-\varepsilon)(1-\varepsilon_1)}{(1+\varepsilon)\varepsilon_1 \cdot (1+\varepsilon)(1-\varepsilon_0) + (1-\varepsilon)\varepsilon_0 \cdot (1-\varepsilon)(1-\varepsilon_1)} \\ &= \frac{2\varepsilon(\varepsilon_1 + \varepsilon_0 - 2\varepsilon_0\varepsilon_1) + (1+\varepsilon^2)(\varepsilon_1 - \varepsilon_0)}{(1+\varepsilon^2)(\varepsilon_1 + \varepsilon_0 - 2\varepsilon_0\varepsilon_1) + 2\varepsilon(\varepsilon_1 - \varepsilon_0)} \\ &\leq \frac{2\varepsilon(\varepsilon_1 + \varepsilon_0 - 2\varepsilon_0\varepsilon_1) + (1+\varepsilon^2)(\varepsilon_1 - \varepsilon_0)}{(1+\varepsilon^2)(\varepsilon_1 + \varepsilon_0 - 2\varepsilon_0\varepsilon_1)} \\ &= \frac{\varepsilon_1 - \varepsilon_0}{\varepsilon_0(1-\varepsilon_1) + \varepsilon_1(1-\varepsilon_0)} + \frac{2\varepsilon}{1+\varepsilon^2}. \end{aligned}$$

Using Lemma 5, we get

$$\text{PredAdv}(X \mid V, Y = \Delta) \leq 1 - \left(1 - \frac{\varepsilon_1 - \varepsilon_0}{\varepsilon_0(1-\varepsilon_1) + \varepsilon_1(1-\varepsilon_0)} - \frac{2\varepsilon}{1+\varepsilon^2}\right) (1-q)^2.$$

Let  $U_0$  and  $U_1$  be the additional information a dishonest sender gets in the two executions of the PassiveWBSC. We have  $U = (X_0, X_1, U_0, U_1)$ . For  $j \in \{0, 1\}$ , we have

$$\delta(P_{X_j U_j | Y_j = X_j}, P_{X_j U_j | Y_j \neq X_j}) \leq p.$$

We can apply Lemma 6, and get

$$\delta(P_{XU | Y = \Delta}, P_{XU | Y \neq \Delta}) \leq 1 - (1-p)^2.$$

□

The following Corollary follows from Corollary 1 and Theorem 5, using  $1 - (1-x)^n \leq nx$ .

**Corollary 2.** Let  $\varepsilon_0 \leq \varepsilon_1$ ,  $p$ ,  $q$  and  $\varepsilon$  be constants, and let

$$\begin{aligned} d_0 &:= \min(2\varepsilon_0(1 - \varepsilon_0), 2\varepsilon_1(1 - \varepsilon_1)) , \\ d_1 &:= \max(2\varepsilon_0(1 - \varepsilon_0), 2\varepsilon_1(1 - \varepsilon_1), \varepsilon_0(1 - \varepsilon_1) + \varepsilon_1(1 - \varepsilon_0)) , \\ w &:= \frac{1}{d_1(1 - d_0) + d_0(1 - d_1)} , \\ \varepsilon' &:= \frac{\varepsilon_1 - \varepsilon_0}{\varepsilon_0(1 - \varepsilon_1) + \varepsilon_1(1 - \varepsilon_0)} + \frac{2\varepsilon}{1 + \varepsilon^2} , \\ \bar{\varepsilon} &:= \frac{\varepsilon_1^2}{\varepsilon_1^2 + (1 - \varepsilon_1)^2} . \end{aligned}$$

If at least one of the conditions

$$4p + 2q + \varepsilon' + (d_1 - d_0)w + 2\bar{\varepsilon} \leq 0.24 , \quad 22q + 11\varepsilon' + 22\bar{\varepsilon} < d_0(1 - d_1)w(1 - p)^4 ,$$

$$88p + 22(d_1 - d_0)w + 44\bar{\varepsilon} < (1 - \varepsilon')(1 - q)^2 , \quad 196p + 98q + 49\varepsilon' + 49(d_1 - d_0)w < (1 - 2\bar{\varepsilon})^2$$

holds, then there exists a protocol that uses  $(\varepsilon, \varepsilon_0, \varepsilon_1, p, q)$ -PassiveWBSC and efficiently implements OT secure in the semi-honest model.

### 4.3 An Example: The Unfair Noisy Channel

We will now show that the *passive unfair noisy channel* from is a special case of a PassiveWBSC.

**Definition 4** ([DKS99, DFMS04]). Let  $0 \leq \gamma \leq \delta < \frac{1}{2}$ . A  $(\delta, \gamma)$ -PassiveUNC is a primitive that takes as input  $x \in \{0, 1\}$  from the sender and outputs  $y \in \{0, 1\}$  to the receiver, where  $y \neq x$  with probability  $\delta$ . Let  $\mu := \frac{\delta - \gamma}{1 - 2\gamma}$ . If the sender is cheating, then the channel first calculates  $u$  such that  $u \neq x$  has a probability  $\gamma$ , and then  $y$  such that  $y \neq u$  has a probability of  $\mu$ , and sends  $u$  to the sender and  $y$  to the receiver. If the receiver is cheating, then the channel first calculates  $v$  such that  $v \neq x$  has a probability  $\mu$ , and then  $y$  such that  $y \neq v$  has a probability of  $\gamma$ , and sends  $(y, v)$  to the receiver.

Note that no matter who cheats,  $y \neq x$  has always the same probability  $\delta$ .

**Lemma 7.** Let

$$p := \frac{(1 - \delta)\delta - (1 - \gamma)\gamma}{(1 - 2\gamma)\delta(1 - \delta)} .$$

If the sender chooses his input uniformly, then  $(\delta, \gamma)$ -PassiveUNC is a  $(0, \delta, \delta, p, p)$ -PassiveWBSC.

*Proof.*

$$\begin{aligned} \delta(P_{UX|Y=X}, P_{UX|Y \neq X}) &= \Pr[U = X | Y = X] - \Pr[U = X | Y \neq X] \\ &= 2\Pr[U = X = 0 | Y = X] - 2\Pr[U = X = 0 | Y \neq X] \\ &= \frac{(1 - \gamma)(1 - \mu)}{1 - \delta} - \frac{\gamma(1 - \mu)}{\delta} = p . \end{aligned}$$

Furthermore, for all  $y \in \{0, 1\}$

$$\begin{aligned} \delta(P_{V|X=0, Y=y}, P_{V|X=1, Y=y}) &= \Pr[V = y | X = y, Y = y] - \Pr[V = y | X \neq y, Y = y] \\ &= \frac{(1 - \mu)(1 - \gamma)}{1 - \delta} - \frac{(1 - \mu)\gamma}{\delta} = p . \end{aligned}$$

□

Note, however, that the bounds that we get using our results are not as good as the bounds from [DKS99, DFMS04].

## 5 WEC in the Malicious Model

The assumption that the adversary is semi-honest and therefore follows the protocol is quite strong and often too strong. As shown in [GMW87], there exist compilers that can convert protocols which are only secure in the semi-honest model into protocols that are also secure in the malicious model. The basic idea is that at the beginning, the players are committed to all the secret data they have, and after every computation step they do, they commit to the newly computed values and show with a zero-knowledge proof that the new committed value contains indeed the correct value, according to the protocol. To implement this in our setting, we need two things: A bit commitment protocol, and a protocol that implements a committed version of the passive weak noisy channel. Hence, for any weak noisy channel in the active model, we need to show that it implies bit commitment and a committed version of either **PassiveWEC** or **PassiveWBSC** for parameters that allow us to achieve OT in the semi-honest model. (See also [DFMS04] for a more detailed discussion.)

Defining a weak noisy channel in the malicious model turns out to be much more tricky than in the semi-honest model. It is possible to define them in the same way as in the semi-honest model, however we think that this would not give a very realistic model. For example, the dishonest player probably may choose an attack where he does not get the output of the honest player. Therefore, we think that it is preferable to state the security conditions such that the malicious player does not need to get the value of the honest player. In the following we will do this for the WEC. For the WBSC, we were not able to come up with a simple definition.

**Definition 5** (WEC, malicious model).  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC is a primitive with the following properties.

- *Correctness*: If both players are honest, then the sender has output  $X \in \{0, 1\}$  and the receiver has output  $Y \in \{0, 1, \Delta\}$ , where  $\Pr[Y = \Delta] \in [d_0, d_1]$  and  $\Pr[Y \neq X \mid Y \neq \Delta] \leq \varepsilon$ .
- *Receiver Security*: If the receiver is honest, then for all dishonest sender with auxiliary input  $z$  and output  $U$ , the receiver has output  $Y \in \{0, 1, \Delta\}$  where  $\Pr[Y = \Delta] \in [d_0, d_1]$  and  $\delta(P_{U|Z=z, Y \neq \Delta}, P_{U|Z=z, Y = \Delta}) \leq p$ .
- *Sender Security*: If the sender is honest, then for all dishonest receiver with auxiliary input  $z$  and output  $V$ , the sender has output  $X \in \{0, 1\}$  and  $\text{PredAdv}(X \mid V, Z = z) \leq g$ .

Note that the parameter  $g$  is different from the parameter  $q$  in the semi-honest case, because we do not condition on the event  $Y = \Delta$ . The honest receiver can guess  $X$  using  $f(Y) := Y$  if  $Y \neq \Delta$ , and either 0 or 1 if  $Y = \Delta$ . We get  $\text{PredAdv}(X \mid Y) \geq (1 - 2\varepsilon)(1 - d_1)$ . Therefore, an ActiveWEC can only be implemented if  $g \geq (1 - 2\varepsilon)(1 - d_1)$ .

### 5.1 Simulation

Using the same simulation as for the semi-honest case, we get

**Theorem 6.** For any  $d, \varepsilon, p$  and  $g$ , where

$$dp + g + 2\varepsilon \geq 1 \quad \wedge \quad g \geq (1 - 2\varepsilon)(1 - d),$$

$(d, d, p, g, \varepsilon)$ -ActiveWEC is simulatable in the malicious model, given that the players have access to a source of trusted shared randomness.

*Proof.* First of all, using coin-toss, it is easy to make Protocol SimWEC work in the malicious model. The proof is very similar to the proof of Theorem 2. We have

$$\begin{aligned} \delta(P_{U|Y \neq \Delta}, P_{U|Y = \Delta}) &\leq |\Pr[M = X \mid T \neq \Delta] - \Pr[M = X \mid T = \Delta]| \\ &= \frac{1 - g - 2\varepsilon}{d} \leq p. \end{aligned}$$

$g$  is the probability with which the receiver gets  $X$ , and hence we have  $\text{PredAdv}(X \mid M) \leq g$ .  $\square$

## 5.2 Bit Commitment

Our commitment protocol takes parameters  $n, c, m, \ell$  and  $\kappa$ , where  $n$  is the number of instances used,  $c$  the error-tolerance of the protocol,  $\ell$  the number of bits committed to, and  $\kappa$  the error. Let  $c := n^{-1/3}$ , and

$$\kappa := \exp(-2(1 - d_1 - c)nc^2).$$

Let  $a$  be the maximum value that satisfies

$$(1 - d) \cdot a - \sqrt{\frac{a}{2}} \cdot \ln \frac{1}{\kappa} \leq (\varepsilon + c)(1 - d)n$$

for all  $d \in [d_0 - c, d_1 + c]$ . Let

$$m := (d_1 p + c)n + 2a + 1$$

and let  $\mathcal{C} \subset \{0, 1\}^n$  be a  $(n, k, m)$ -linear code<sup>5</sup>, i.e., with  $2^k$  elements and minimal distance  $m$ . Let

$$\ell := k - (g + c) \cdot n - 3 \log(1/\kappa)$$

and  $n$  be big enough such that  $\ell > 0$ . Let  $H$  be a parity-check matrix of  $\mathcal{C}$  and  $\text{ext} : \mathcal{R} \times \{0, 1\}^n \rightarrow \{0, 1\}^\ell$  be a 2-universal hash function. In the following protocol, the sender is the committer.

Protocol ActiveWECtoBC

### Commit( $\mathbf{b}$ ).

- The parties execute ActiveWEC  $n$  times. The committer gets  $x = (x_0, \dots, x_{n-1})$ , and the receiver gets  $y = (y_0, \dots, y_{n-1})$ .
- The committer chooses  $r \in \mathcal{R}$  uniformly at random and sends it to the receiver.
- The committer sends  $s := (H(x), b \oplus \text{ext}(r, x))$  to the receiver.

### Open.

- The committer sends  $(b, x)$  to the receiver.
- Let  $n_\Delta$  be the number of  $y_i$  equal to  $\Delta$ . The receiver checks that  $n_\Delta/n \in [d_0 - c, d_1 + c]$  and that the number  $i$  where  $y_i \neq x_i$  and  $y_i \neq \Delta$  is smaller than  $(n - n_\Delta)(\varepsilon + c)$ . He also checks that  $s = (H(x), b \oplus \text{ext}(r, x))$ . If this is the case, he accepts, and rejects otherwise.

In the protocol, the committer has to send the receiver the parity-check of a code, because then the committer cannot guess with probability more than  $\varepsilon$  more than one value  $x$  that passes the test of the receiver in the open phase. The committer extracts a string of size  $\ell$  from  $x$ , where  $\ell$  is chosen small enough such that the receiver has almost no information about it.

<sup>5</sup>Since we do not have to decode  $\mathcal{C}$ , this could be a random linear code.

**Theorem 7.** *Protocol ActiveWECtoBC implements a commitment with an error of  $4\kappa$ , out of  $n$  instances of  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC.*

The statement of Theorem 7 follows from Lemma 8, 9 and 12.

**Lemma 8.** *If both players are honest, then Protocol ActiveWECtoBC aborts with a probability at most  $3\kappa$ .*

*Proof.* From Lemma 23 follows that the number of  $y_i = \Delta$  is outside the interval  $[(d_0 - c) \cdot n, (d_1 + c) \cdot n]$  with probability at most  $2 \exp(-2nc^2) \leq 2\kappa$ . Given that this is not the case, the probability that the number of values  $y_i$  that is not equal to  $\Delta$  nor  $x_i$  is bigger than  $(\varepsilon + c) \cdot (n - n_\Delta)$  is at most  $\exp(-2(n - n_\Delta)c^2) \leq \exp(-2(1 - d_1 - c)nc^2) \leq \kappa$ .  $\square$

**Lemma 9.** *Protocol ActiveWECtoBC is binding with probability  $1 - 4\kappa$ .*

*Proof.* Let  $d := n_\Delta/n$ . According to Lemma 3, for all  $i$  there exist random variables  $B_i$ , such that

$$\Pr[B_i = 1 \mid Y_i = \Delta] = \Pr[B_i = 1 \mid Y_i \neq \Delta] = p,$$

and

$$P_{U_i \mid Y_i = \Delta, B_i = 0} = P_{U_i \mid Y_i \neq \Delta, B_i = 0}.$$

Let the random variable  $Y'_i \in \{0, 1\}$  be defined as follows: If  $Y_i \neq \Delta$ , let  $Y'_i = Y_i$ , and let  $Y'_i$  be chosen randomly from  $\{0, 1\}$  otherwise, such that  $\Pr[Y'_i = 1 \mid Y_i = \Delta] = \Pr[Y'_i = 1 \mid Y_i \neq \Delta]$ . ( $Y'_i$  is therefore independent of the event  $Y_i = \Delta$ .) Let us assume that the sender additionally receives the values  $B_i$  and  $Y'_i$ .

We divide the  $n$  instances into 3 sets. Let  $\mathcal{S}_0$  be the set of values where  $B_i = 1 \wedge Y_i = \Delta$ ,  $\mathcal{S}_1$  the set of values where  $B_i = 1 \wedge Y_i \neq \Delta$ , and  $\mathcal{S}_2$  the set of values where  $B_i = 0$ . The receiver will only accept if  $d \in [d_0 - c, d_1 + c]$ . Since  $\kappa \geq \exp(-2nc^2)$ , it follows from Lemma 23 that with probability  $1 - 3\kappa$ ,  $|\mathcal{S}_0| \leq (dp + c)n$ ,  $|\mathcal{S}_1| \leq ((1 - d)p + c)n$  and  $|\mathcal{S}_2| \leq (1 - p + c)n$ . The sender can freely choose all the values  $x_i$  in set  $\mathcal{S}_0$ , as he knows that the receiver cannot check them. Since the receiver allows a certain amount of errors, the sender may choose a subset of  $\mathcal{S}_1$  of size  $a'$  and a subset of  $\mathcal{S}_2$  of size  $a$ , where  $x_i \neq y'_i$ . We know that the receiver will notice all  $a'$  errors in  $\mathcal{S}_1$ , and it follows from Lemma 23 that with probability  $1 - \kappa$ , he will notice at least

$$a \cdot \left(1 - d - \sqrt{\frac{1}{2a} \cdot \ln \frac{1}{\kappa}}\right) = a \cdot (1 - d) - \sqrt{\frac{a}{2} \cdot \ln \frac{1}{\kappa}}$$

from  $\mathcal{S}_2$ . Therefore, the receiver will only accept with probability at least  $\kappa$ , if

$$a' + a \cdot (1 - d) - \sqrt{\frac{a}{2} \cdot \ln \frac{1}{\kappa}} \leq (\varepsilon + c)(1 - d)n.$$

The sender would only be able to find two values with the same parity-check, if

$$(dp + c)n + 2(a' + a) \geq m.$$

The best strategy for the sender is to choose  $a' = 0$ , and to make  $a$  maximal. It follows from the definition of  $m$  that the sender cannot find two such values. The statement follows.  $\square$

To proof that the protocol is hiding we need some additional lemmas. The *conditional smooth min-entropy of  $X$  given  $Y$*  [RW05] is defined as

$$H_{\min}^\varepsilon(X \mid Y) := \max_{\Omega: \Pr[\Omega] \geq 1 - \varepsilon} \min_{xy} (-\log P_{X\Omega \mid Y=y}(x)).$$

**Lemma 10** ([Cac97, MW97]).  $H_{\min}^{\varepsilon+\varepsilon'}(X | YZ) \geq H_{\min}^{\varepsilon}(XY | Z) - \log |\mathcal{Y}| - \log(1/\varepsilon')$ .

We say that  $X$  is  $\varepsilon$ -close to uniform with respect to  $Y$ , if  $\delta(P_{XY}, P_U P_Y) \leq \varepsilon$ , where  $P_U$  is the uniform distribution.

**Lemma 11** (Leftover hash lemma [BBR88, ILL89]). *Let  $X$  be a random variable over  $\mathcal{X}$  and let  $m > 0$ . Let  $h : \mathcal{R} \times \mathcal{X} \rightarrow \{0, 1\}^m$  be a 2-universal hash function. If*

$$m \leq H_{\min}^{\varepsilon}(X | Y) - 2 \log(1/\varepsilon') ,$$

*then for  $R$  uniform over  $\mathcal{R}$ ,  $h(R, X)$  is  $(\varepsilon + \varepsilon')$ -close to uniform with respect to  $(R, Y)$ .*

**Lemma 12.** *Protocol ActiveWECtoBC is hiding with probability  $1 - 3\kappa$ .*

*Proof.* The sender holds  $X = (X_1, \dots, X_n)$ , and the receiver  $V = (V_1, \dots, V_n)$ ,  $S$  and the auxiliary input  $z$ . Using Lemma 2, for every pair  $(X_i, V_i)$ , there exists a random variable  $B_i$ , such that  $\Pr[B_i = 1] = g$  and  $X_i$  is uniform, given  $(V_i, B_i = 0, Z = z)$ . From Lemma 23 follows that with probability  $1 - \kappa$ , the number of  $B_i = 0$  is at least  $n(1 - g - c)$  and therefore

$$H_{\infty}^{\kappa}(X | V, Z = z) \geq n(1 - g - c) .$$

Using Lemma 10, we get

$$H_{\infty}^{2\kappa}(X | V, S, Z = z) \geq n(1 - g - c) - (n - k) - \log(1/\kappa) .$$

Finally, we can apply Lemma 11, and get that  $\text{ext}(R, X)$  is  $3\kappa$ -close to uniform, since

$$\ell \leq H_{\infty}^{2\kappa}(X | V, S, Z = z) - 2 \log(1/\kappa) .$$

This implies that the protocol is hiding with probability  $1 - 3\kappa$ . □

Note that for any  $e > 0$ , and  $k \leq (1 - h(m/n))n - e$ , a random linear  $(n, k)$ -code has a minimal distance of at least  $m$  with probability at least  $1 - 2^{-e}$ . If we choose a random linear code and let  $n \rightarrow \infty$ , then  $b/n \rightarrow \varepsilon$ , and hence  $m/n \rightarrow d_1 p + 2\varepsilon$ . From the property of the random linear code, we get  $k/n \rightarrow 1 - h(d_1 p + 2\varepsilon)$ . We need  $\ell > 0$ , which is equivalent to  $g < k/n$ . We get the following corollary.

**Corollary 3.** *For any  $d_1, d_1, \varepsilon, p$  and  $q$  where*

$$d_1 p + 2\varepsilon < \frac{1}{2}, \quad \text{and} \quad g + h(d_1 p + 2\varepsilon) < 1 ,$$

*$(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC implies bit commitment where the sender is the committer.*

Our bound is optimal for  $p = 0 \wedge \varepsilon = 0$ . Otherwise, it does not reach the simulation bound, since  $h(x) > x$  for all  $0 < x < \frac{1}{2}$ .

### 5.2.1 Other direction

We will now present a bit commitment in the other direction, where the receiver is the committer. Let  $c := n^{-1/3}$ , and  $\kappa := \exp(-2(1 - d_1 - c)nc^2)$ . Let

$$m := \max_{d \in [d_0 - c, d_1 + c]} 2(g + d + c - 1) \cdot n + 4a(d) + 1 ,$$

where  $a(d)$  is the maximal value that satisfies

$$\frac{a(d)}{2} - \sqrt{\frac{a(d)}{2} \cdot \ln \frac{1}{\kappa}} \leq (\varepsilon + c)(1 - d)n .$$

Let  $\mathcal{C} \subset \{0, 1\}^n$  be a  $(n, k, m)$ -linear code. Let  $d' = \min(d_0, 1 - d_1)$  and

$$\ell := H_{\min}^{\kappa}(W) - (n - k) - 3 \log(1/\kappa) ,$$

where  $W = (W_0, \dots, W_{m-1})$ , and all  $W_i$  are independent and take on 2 with probability  $p$ , 1 with probability  $(1 - p) \cdot d'$ , and 0 with probability  $(1 - p) \cdot (1 - d')$ . Let  $n$  be big enough such that  $\ell > 0$ . Let  $H$  be the parity-check matrix of  $\mathcal{C}$  and  $\text{ext} : \mathcal{R} \times \{0, 1\}^n \rightarrow \{0, 1\}^{\ell}$  be a 2-universal hash function. In the following protocol, the sender is the receiver of the commitment, and the receiver is the committer. Let  $\hat{y}_i = 0$  if  $y_i = \Delta$  and  $\hat{y}_i = 1$  otherwise.

Protocol `InvActiveWECtoBC`

**Commit(b).**

- The parties execute `ActiveWEC`  $n$  times. The receiver gets  $x = (x_0, \dots, x_{n-1})$ , and the committer gets  $y = (y_0, \dots, y_{n-1})$ .
- The committer chooses  $r \in \mathcal{R}$  uniformly at random and sends  $r$  and  $s := (H(\hat{y}), b \oplus \text{ext}(r, \hat{y}))$  to the receiver.

**Open.**

- The committer sends  $(b, y)$  to the receiver.
- Let  $n_{\Delta}$  be the number of  $y_i$  equal to  $\Delta$ . The receiver checks that  $n_{\Delta}/n \in [d_0 - c, d_1 + c]$  and that the number  $i$  where  $y_i \neq x_i$  and  $y_i \neq \Delta$  is smaller than  $(n - n_{\Delta})(\varepsilon + c)$ . He also checks that  $s = (H(\hat{y}), b \oplus \text{ext}(r, \hat{y}))$ . If this is the case, he accepts, and rejects otherwise.

The proof for correctness is the same as in protocol `ActiveWECtoBC`.

**Lemma 13.** *If both players are honest, then Protocol `InvActiveWECtoBC`-inverse aborts with a probability at most  $3\kappa$ .*

**Lemma 14.** *Protocol `InvActiveWECtoBC` is binding with probability  $1 - 2\kappa$ .*

*Proof.* Let  $d := n_{\Delta}/n$ . According to Lemma 3, for all  $i$  there exist random variables  $B_i$ , such that  $\Pr[B_i = 1] = g$  and

$$P_{V_i|X_i=0, B_i=0} = P_{V_i|X_i=1, B_i=0} .$$

Let us assume that the committer gets the value  $X_i$ , if  $B_i = 1$ . In the open phase, he has to calculate values  $Y_i$  out of  $V_i$  that satisfies the conditions. Let  $a$  be the number of positions where  $b_i = 0$  and  $y_i \neq \Delta$ . Since the committer has no information about  $X_i$  at these positions, with probability  $1 - \kappa$ ,  $Y$  will have at least  $\frac{a}{2} - \sqrt{\frac{a}{2} \log \frac{1}{\kappa}}$  errors. Therefore, the receiver only accepts with probability at least  $\kappa$ , if

$$\frac{a}{2} - \sqrt{\frac{a}{2} \log \frac{1}{\kappa}} \leq (\varepsilon + c)(1 - d)n .$$

With probability  $1 - \kappa$ , the number of positions where  $B_i = 0$  is at least  $(1 - g - c)n$ , from which all but  $a$  map to a  $y_i = \Delta$ . Therefore, at most  $(d - (1 - g - c)) \cdot n + a$  values where  $B_i = 1$  map to a  $y_i = \Delta$ . It follows that the distance between two strings  $\hat{Y}_0$  and  $\hat{Y}_1$  is smaller than  $m$ . There exists only one value that has the given parity-check.  $\square$

**Lemma 15.** *Protocol ActiveWECtoBC is hiding with probability  $1 - 3\kappa$ .*

*Proof.* The sender holds  $X = (X_1, \dots, X_n)$ , and the receiver  $V = (V_1, \dots, V_n)$ ,  $S$  and the auxiliary input  $z$ . Using Lemma 3, the receiver get to know  $\hat{Y}_i$  with probability  $p$ . Otherwise, it takes on 1 with probability  $d_i \in [d_0, d_1]$  and 0 otherwise. We have  $H_\infty^\kappa(\hat{Y} | U, Z = z) \geq H_\infty^\kappa(W)$ . Using Lemma 10, we get

$$H_\infty^{2\kappa}(\hat{Y} | U, S, Z = z) \geq H_\infty^\kappa(W) - (n - k) - \log(1/\kappa).$$

Finally, we can apply Lemma 11, and get that  $\text{ext}(R, \hat{Y})$  is  $3\kappa$ -close to uniform, since

$$\ell \leq H_\infty^\kappa(\hat{Y} | U, S, Z = z) - 2\log(1/\kappa).$$

This implies that the protocol is hiding with probability  $1 - 3\kappa$ .  $\square$

We get

**Theorem 8.** *Protocol InvActiveWECtoBC implements a commitment with an error of  $3\kappa$ , out of  $n$  instances of  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC.*

Let  $\hat{d} = d_1$  if  $\varepsilon < 1/4$  and  $\hat{d} = d_0$  otherwise. For  $n \rightarrow \infty$ , we have  $H_{\min}^\kappa(W) \rightarrow (1 - p)h(d')n$ ,

$$m \rightarrow \max_{d \in [d_0, d_1]} 2(g + d - 1 + 4\varepsilon(1 - d)) \cdot n = 2(g + \hat{d} - 1 + 4\varepsilon(1 - \hat{d})) \cdot n$$

and

$$k/n \rightarrow 1 - h(2(g + \hat{d} - 1 + 4\varepsilon(1 - \hat{d}))).$$

We need  $\ell > 0$ , which is equivalent to

$$(1 - p)h(d') > h(2(g + \hat{d} - 1 + 4\varepsilon(1 - \hat{d}))).$$

We get the following corollary.

**Corollary 4.** *Let  $d_0 < d_1$ ,  $\varepsilon \in [0, \frac{1}{2}]$ ,  $p, q \in [0, 1]$ , and let  $d' = \min(d_0, 1 - d_1)$ , and  $\hat{d} = d_1$  if  $\varepsilon < 1/4$  and  $\hat{d} = d_0$  otherwise. If*

$$g + \hat{d} - 1 + 4\varepsilon(1 - \hat{d}) < \frac{1}{4}, \quad \text{and} \quad (1 - p)h(d') > h(2(g + \hat{d} - 1 + 4\varepsilon(1 - \hat{d}))),$$

*then  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC implies bit commitment where the receiver is the committer.*

### 5.3 Committed PassiveWEC from ActiveWEC

In the following, we present the protocol to implement a committed version of PassiveWEC in the malicious model, using ActiveWEC. It uses a similar idea already used in [DFMS04]: The players execute ActiveWEC  $n$  times and commit to their output values. Then, they open all except one that is chosen at random, and check if the statistics are fine. If they are, then also the statistics of the remaining instance is fine.

The following lemma is essential to the proof, because it can be used to bound the parameter  $p$  for any committed value  $Y$  produced by the dishonest receiver, if he passes the test by the honest sender. It is easy to verify that the lemma is tight if  $V$  is equal to  $X$  with probability  $p$  and  $\Delta$  otherwise.

**Lemma 16.** Let  $P_{XV}$  be a distribution over  $\{0, 1\} \times \mathcal{V}$ . If  $\text{PredAdv}(X | V) \leq g$ , then for any function  $Y = f(V) \in \{0, 1, \Delta\}$  where  $\Pr[Y = \Delta] \in [d_0, d_1]$  and  $\Pr[Y \neq X | Y \neq \Delta] \leq \varepsilon$ , we have

$$\text{PredAdv}(X | V, Y = \Delta) \leq \frac{g - (1 - 2\varepsilon)(1 - d_1)}{d_1}.$$

*Proof.* Let  $B$  be the random variable defined by Lemma 2. We have  $\Pr[B = 1] = g$  and  $\text{PredAdv}(V | X, B = 0) = 0$ . For any  $Y = f(V)$ , we have

$$\Pr[Y \neq X | Y \neq \Delta] \geq \frac{1}{2} \cdot \frac{\Pr[Y \neq \Delta \wedge B = 0]}{\Pr[Y \neq \Delta]}.$$

Therefore, it must hold that  $2\varepsilon \Pr[Y \neq \Delta] \geq \Pr[Y \neq \Delta \wedge B = 0]$ . From

$$\Pr[Y \neq \Delta \wedge B = 1] = \Pr[Y \neq \Delta] - \Pr[Y \neq \Delta \wedge B = 0]$$

and

$$\Pr[Y = \Delta \wedge B = 1] = g - \Pr[Y \neq \Delta \wedge B = 1]$$

we get

$$\Pr[Y = \Delta \wedge B = 1] = g - \Pr[Y \neq \Delta] + \Pr[Y \neq \Delta \wedge B = 0].$$

Therefore

$$\begin{aligned} \Pr[B = 1 | Y = \Delta] &= \frac{g - \Pr[Y \neq \Delta] + \Pr[Y \neq \Delta \wedge B = 0]}{\Pr[Y = \Delta]} \\ &\leq \frac{g - \Pr[Y \neq \Delta] + 2\varepsilon \Pr[Y \neq \Delta]}{\Pr[Y = \Delta]} \\ &\leq \frac{g - (1 - 2\varepsilon)(1 - \Pr[Y = \Delta])}{\Pr[Y = \Delta]} = 1 - 2\varepsilon - \frac{1 - g - 2\varepsilon}{\Pr[Y = \Delta]} \\ &\leq 1 - 2\varepsilon - \frac{1 - g - 2\varepsilon}{d_1} = \frac{g - (1 - 2\varepsilon)(1 - d_1)}{d_1}. \end{aligned}$$

Using Lemma 4, we get

$$\begin{aligned} \text{PredAdv}(X | V, Y = \Delta) &\leq \Pr[B = 0 | Y = \Delta] \cdot \text{PredAdv}(X | V, B = 0, Y = \Delta) \\ &\quad + \Pr[B = 1 | Y = \Delta] \cdot \text{PredAdv}(X | V, B = 1, Y = \Delta) \\ &\leq \Pr[B = 1 | Y = \Delta]. \end{aligned}$$

□

In addition to ActiveWEC, our protocol needs bit commitments and coin-tosses. Coin-toss can easily be implemented using bit commitments.

Again,  $c$  is the error-tolerance, and  $\kappa$  is the error in the protocol. We choose  $c := n^{-1/3}$  and  $\kappa := \exp(-2(1 - d_1 - c)nc^2)$ . Furthermore, let  $n$  be big enough such that  $c \geq 1/((1 - d_1 - c)n)$ .

Protocol ActiveToPassiveWEC

1. The sender and the receiver execute ActiveWEC  $n$  times. The sender gets  $(x_0, \dots, x_{n-1})$ , and the receiver  $(y_0, \dots, y_{n-1})$ .
2. Both players commit to their values.
3. Using coin-toss, they randomly select one instance  $s$  of the  $n$  instances.

4. They open all commitments, except for instance  $s$ . If any of the players does not accept one opening of a commitment, they abort.
5. Let  $n_\Delta$  be the number of  $y_i$  that is equal to  $\Delta$ . They check if  $n_\Delta$  is in the interval  $[(d_0 - c) \cdot n - 1, (d_1 + c) \cdot n]$ , and the number of  $y_i$  that is not equal to  $\Delta$  nor  $x_i$  is smaller than  $(\varepsilon + c) \cdot (n - n_\Delta)$ . If not, they abort.
6. The sender outputs  $x := x_s$ , the receiver  $y := y_s$ .

**Theorem 9.** *Protocol ActiveToPassiveWEC implements a committed version of*

$$\left( d_0 - 2c, d_1 + 2c, p, \frac{g - (1 - 2\varepsilon)(1 - d_1) + 6c}{d_1}, \varepsilon + 2c \right)\text{-PassiveWEC},$$

with an error of at most  $3\kappa$  in the malicious model. It uses coin-toss, bit commitment and  $n$  independent instances of  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC.

The statement of Theorem 9 follows from Lemmas 17, 19 and 20.

**Lemma 17.** *If both players are honest, then Protocol ActiveToPassiveWEC aborts with a probability smaller than  $3\kappa$ .*

*Proof.* From Lemma 23 follows that the number of  $y_i = \Delta$  is outside the interval  $[(d_0 - c) \cdot n - 1, (d_1 + c) \cdot n]$  with probability at most  $2 \exp(-2nc^2) \leq 2\kappa$ . Given that this is not the case, the probability that the number of values  $y_i$  that is not equal to  $\Delta$  nor  $x_i$  is bigger than  $(\varepsilon + c) \cdot (n - n_\Delta)$  is at most  $\exp(-2(n - n_\Delta)c^2) \leq \exp(-2(1 - d_1 - c)nc^2) \leq \kappa$ . If these two conditions hold, then the players will not abort, checking all but one values.  $\square$

**Lemma 18.** *If neither of the players aborts the protocol, then both are committed to values  $X$  and  $Y$ , where  $\Pr[Y = \Delta] \in [d_0 - 2c, d_1 + 2c]$  and  $\Pr[Y \neq X \mid Y \neq \Delta] \leq \varepsilon + 2c$ .*

*Proof.* The number of values  $y_i = \Delta$  is either  $n_\Delta$  or  $n_\Delta + 1$ . Since  $s$  is chosen at random, we have

$$\Pr[Y = \Delta] \in \left[ \frac{n_\Delta}{n}, \frac{n_\Delta + 1}{n} \right] \subseteq \left[ d_0 - c - \frac{1}{n}, d_1 + c + \frac{1}{n} \right] \subseteq [d_0 - 2c, d_1 + 2c],$$

and

$$\Pr[Y \neq X \mid Y \neq \Delta] \leq \frac{(\varepsilon + c)(n - n_\Delta) + 1}{n - n_\Delta} = \varepsilon + c + \frac{1}{n - n_\Delta} \leq \varepsilon + 2c.$$

$\square$

**Lemma 19.** *If the receiver is honest, then for any malicious sender, the execution of Protocol ActiveToPassiveWEC is either aborted or the sender and the receiver are committed to values  $X$  and  $Y$ , where  $\delta(P_{XU|Y \neq \Delta}, P_{XU|Y = \Delta}) \leq p$ .*

*Proof.* The adversary calculates  $X$  from  $U$ . It follows that  $\delta(P_{XU|Y \neq \Delta}, P_{XU|Y = \Delta}) \leq p$ .  $\square$

**Lemma 20.** *If the sender is honest, then for any malicious receiver, the execution of Protocol ActiveToPassiveWEC is either aborted or the sender and the receiver are committed to values  $X$  and  $Y$  where*

$$\text{PredAdv}(X \mid V, Y = \Delta) \leq \frac{g - (1 - 2\varepsilon)(1 - d_1) + 6c}{d_1}.$$

*Proof.* We can apply Lemmas 16, 18 and get

$$\text{PredAdv}(X \mid V, Y = \Delta) \leq \frac{g - (1 - 2\varepsilon - 4c)(1 - d_1 - 2c)}{d_1 + 2c} \leq \frac{g - (1 - 2\varepsilon)(1 - d_1) + 6c}{d_1}.$$

□

Note that  $c$  is only polynomially small and cannot be made negligible. Here we see an advantage of our definition compared to the **PassiveUNC** in [DKS99, DFMS04]: We do not have to introduce the additional error parameter  $p(k)$  as it has to be done for the committed version of the **PassiveUNC**, nor do we have to add an additional amplification step to the reduction to make this additional error negligible. The following corollary follows from Corollary 1 and Theorem 9.

**Corollary 5.** *Let  $d_0 \leq d_1$ ,  $p$ ,  $g$  and  $\varepsilon$  be constants, and let  $w := 1/(d_1(1 - d_0) + d_0(1 - d_1))$  and  $q := \frac{2(g - (1 - 2\varepsilon)(1 - d_1))}{d_1 + g - (1 - 2\varepsilon)(1 - d_1)}$ . If at least one of the conditions*

$$\begin{aligned} p + q + w(d_1 - d_0) + 2\varepsilon < 0.24, \quad 11q + 22\varepsilon < d_0(1 - d_1)w(1 - p)^2, \\ 44p + 22w(d_1 - d_0) + 44\varepsilon < 1 - q, \quad 98p + 49q + 49w(d_1 - d_0) < (1 - 2\varepsilon)^2 \end{aligned}$$

*holds, then there exists a protocol that uses  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC and bit commitments and efficiently implements OT secure in the malicious model.*

To achieve any two party computation from a  $(d_0, d_1, p, g, \varepsilon)$ -ActiveWEC, the conditions of Corollary 5 and Corollary 3 must be satisfied simultaneously.

## 6 Computational Case

Until now, all proves have been made under the assumption of unbounded adversaries. We will now shortly outline how they could be adapted for polynomially bounded adversaries.

Instead of  $\text{PredAdv}(X \mid Y) \leq p$ , we only require that all *polynomial time* algorithms  $A$  satisfy

$$2 \Pr[A(Y) = X] - 1 \leq q(k) + \text{negl}(k),$$

where  $k$  is the security parameter. In the same way, instead of  $\delta(P_{Y|X=0}, P_{Y|X=1}) \leq p$ , we require that all polynomial time algorithms  $A$  satisfy

$$|\Pr[A(Y) = 1 \mid X = 0] - \Pr[A(Y) = 1 \mid X = 1]| \leq p(k) + \text{negl}(k).$$

The main tools for the proof in the computational setting are the computational oblivious transfer amplification results from [Wul07] and the secrecy degradation lemma from [HR08], which is a computational version of Lemma 6. Furthermore, the following Lemma is needed, which is a computational version of Lemma 5.

**Lemma 21.** *Let functions  $f : \{0, 1\}^k \rightarrow \{0, 1\}^\ell$ ,  $P : \{0, 1\}^k \rightarrow \{0, 1\}$ . Let  $0 \leq a < b < 1$ . Let  $W$  is distributed according to  $P_W$  over  $\{0, 1\}^k$ , where  $\Pr[P(W) = 1] \in [\frac{1}{2}, \frac{1+a}{2}]$ . For any algorithm  $A$ ,*

$$\Pr[A(f(W)) = P(W)] > \frac{1 + b}{2}$$

*implies that*

$$\Pr[A(f(W)) = 1 \mid P(W) = 1] - \Pr[A(f(W)) = 1 \mid P(W) = 0] > \frac{b - a}{1 - a}.$$

*Proof.* Let  $\Pr[P(W) = 1] = \frac{1+a'}{2}$ , where  $a' \in [0, a]$ , and  $p_i = \Pr[A(f(W)) = 1 \mid P(W) = i]$ , for  $i \in \{0, 1\}$ . We have

$$\Pr[A(f(W)) = P(W)] = (1 - p_0) \cdot \frac{1 - a'}{2} + p_1 \cdot \frac{1 + a'}{2} > \frac{1 + b}{2},$$

from which follows

$$(1 + a')p_1 - (1 - a')p_0 > b + a'.$$

Subtracting  $2a'p_1$  on both sides, we get

$$(1 - a')(p_1 - p_0) > b + a' - 2a'p_1.$$

Since  $p_1 \leq 1$  we get

$$p_1 - p_0 > \frac{b - a'}{1 - a'} \geq \frac{b - a}{1 - a}.$$

The statement follows.  $\square$

Using these tools, Theorem 3 and 5 can quite easily be proved in the computational setting. Theorem 9 can be proved in the computational setting using the following lemma, which generalizes Lemma 16 to the computational setting.

**Lemma 22.** *Let functions  $v : \{0, 1\}^k \rightarrow \{0, 1\}^\ell$ ,  $P : \{0, 1\}^k \rightarrow \{0, 1\}$ . Let  $W$  is distributed according to  $P_W$  over  $\{0, 1\}^k$ . There exists an efficient algorithm  $B^{(\cdot, \cdot)}$ , such that for any function  $f : \{0, 1\}^\ell \rightarrow \{0, 1, \Delta\}$  where*

$$\Pr[f(v(W)) = \Delta] \in [d_0, d_1] \quad \wedge \quad \Pr[f(v(W)) \neq P(W) \mid f(v(W)) \neq \Delta] \leq \varepsilon,$$

and algorithm  $A$  where

$$\Pr[A(v(W)) = P(W) \mid f(v(W)) = \Delta] > \frac{1 + q}{2},$$

and we have

$$\Pr[B^{(f, A)}(v(W)) = P(W)] > \frac{1 + d_1q + (1 - 2\varepsilon)(1 - d_1)}{2}.$$

*Proof.* We define  $B^{(f, A)}$  as follows. On input  $v$  he calls  $f$  on  $v$  and gets back  $y$ . If  $y \neq \Delta$ , he outputs  $y$ . Otherwise, he outputs  $A(v)$ . Let  $V = v(W)$ ,  $Y = f(V)$  and  $X = P(W)$ .

$$\begin{aligned} \Pr[B^{(f, A)}(V) = X] &= \Pr[Y = \Delta] \cdot \Pr[A(V) = X \mid Y = \Delta] + \Pr[Y \neq \Delta] \cdot \Pr[Y = X \mid Y \neq \Delta] \\ &> \Pr[Y = \Delta] \cdot \frac{1 + q}{2} + \Pr[Y \neq \Delta] \cdot (1 - \varepsilon) \\ &\geq d_1 \cdot \frac{1 + q}{2} + (1 - d_1) \cdot (1 - \varepsilon) \\ &\geq \frac{1 + d_1q + (1 - 2\varepsilon)(1 - d_1)}{2}. \end{aligned}$$

$\square$

## 7 Conclusions and Open Problems

We gave new, weaker security definitions for the erasure channel and the binary symmetric channel, and showed that they imply oblivious transfer. The advantage of our new definitions is that they allow the use of channels from which the statistics are not known with arbitrary precision, which make it possible to use channels where the parameters come from experimental evidence. Note that together with the computational WOT amplification from [Wul07], our results can also be used in a computational setting.

It seems to be difficult to close the gap between the possibility and the impossibility bounds for OT. But maybe it is possible to get a tight bound for bit commitment. Still missing is a definition of the weak binary symmetric channel in the malicious model. Furthermore, it would be nice to have a bit commitment protocol that works for a weak form of the Gaussian channels.

## A Appendix

**Lemma 23** (Chernoff/Hoeffding bound). *Let  $P_{X_0 \dots X_n} = P_{X_0} \dots P_{X_n}$  be a product distribution with  $X_i \in [0, 1]$ . Let  $\bar{X} := \frac{1}{n} \sum_{i=0}^{n-1} X_i$ , and  $\mu = E[\bar{X}]$ . Then, for any  $\varepsilon > 0$ ,*

$$\Pr[\bar{X} \geq \mu + \varepsilon] \leq \exp(-2n\varepsilon^2), \quad \Pr[\bar{X} \leq \mu - \varepsilon] \leq \exp(-2n\varepsilon^2).$$

**Lemma 24.** *Let  $0 \leq e_0 \leq e_1 \leq 1$ . Then*

$$\max_{c, c' \in [e_0, e_1]} \frac{cc'}{cc' + (1-c)(1-c')} \leq \frac{e_1^2}{e_1^2 + (1-e_1)(1-e_1)}.$$

*Proof.* Let  $f(x, y) := \frac{xy}{xy + (1-x)(1-y)}$ . We have

$$\begin{aligned} \frac{\partial}{\partial x} f(x, y) &= \frac{y(1-y)}{(xy + (1-x)(1-y))^2} \geq 0, \\ \frac{\partial}{\partial y} f(x, y) &= \frac{x(1-x)}{(xy + (1-x)(1-y))^2} \geq 0. \end{aligned}$$

Hence,  $f(x, y)$  is maximized on  $x, y \in [e_0, e_1]$  for  $x = y = e_1$ . □

**Lemma 25.** *Let  $0 \leq d_0 \leq d_1 \leq 1$ . Then*

$$\max_{d, d' \in [d_0, d_1]} \frac{d(1-d')}{d(1-d') + d'(1-d)} \leq \frac{d_1(1-d_0)}{d_1(1-d_0) + d_0(1-d_1)}.$$

*Proof.* Let  $f(x, y) := \frac{x(1-y)}{x(1-y) + x(1-y)}$ . We have

$$\begin{aligned} \frac{\partial}{\partial x} f(x, y) &= \frac{y(1-y)}{(x(1-y) + x(1-y))^2} \geq 0, \\ \frac{\partial}{\partial y} f(x, y) &= \frac{-x(1-x)}{(x(1-y) + x(1-y))^2} \leq 0. \end{aligned}$$

Hence,  $f(x, y)$  is maximized on  $x, y \in [d_0, d_1]$  for  $x = d_1$  and  $y = d_0$ . □

**Lemma 26.** *Let  $0 \leq d_0 \leq d_1 \leq 1$ . Then*

$$\min_{x, y \in [d_0, d_1]} x(1-y) + y(1-x) = \min(2d_0(1-d_0), 2d_1(1-d_1))$$

and

$$\max_{x, y \in [d_0, d_1]} x(1-y) + y(1-x) = \max(2d_0(1-d_0), 2d_1(1-d_1), d_1(1-d_0) + d_0(1-d_1)).$$

*Proof.* Let  $f(x, y) := x(1-y) + y(1-x)$ . We have

$$\frac{\partial}{\partial x} f(x, y) = 1 - 2y, \quad \frac{\partial}{\partial y} f(x, y) = 1 - 2x.$$

Since these functions are linear,  $f(x, y)$  can only be minimized or maximized on one of the four corner points, where both  $x$  and  $y$  are either equal to  $d_0$  or  $d_1$ . Furthermore, if  $d_0 \leq 0.5$  then  $f(d_0, d_0) \leq f(d_0, d_1)$  and  $f(d_0, d_0) \leq f(d_1, d_0)$ . Similarly, if  $d_1 \geq 0.5$ , then  $f(d_1, d_1) \leq f(d_0, d_1)$  and  $f(d_1, d_1) \leq f(d_1, d_0)$ . Therefore, the function can only be at its minimal when  $x = y$ . □
